World Wildlife Crime Report

2024
Preface

I am pleased to present the third edition of UNODC’s World Wildlife Crime Report, which aims to provide a tool to assess and improve responses to this hugely damaging form of criminal activity. The present report covers trends in the illicit wildlife trade, analyses harms and impacts, probes driving factors, and takes stock of responses.

Wildlife crimes are diverse and often devastating in their impact and consequences. They hamper conservation efforts, damage ecosystems, and contribute to undermining our planet’s capacity to mitigate climate change. They also infringe on the essential needs, income opportunities, and cultural rights of local communities, and corrode governance and the rule of law.

Global recognition of this damage has grown steadily, and after two decades of concerted action, there is some cause for optimism. There has been tangible success against trafficking of some iconic species, while cross-border cooperation and criminalization of wildlife crime have both improved.

Nevertheless, the magnitude of this illegal trade remains immense, affecting thousands of species of animals and plants and spanning more than 160 countries and territories. Much more work is urgently needed to tackle challenges both chronic and emerging.

Seizures are not enough to understand the problem, nor to end it, and wildlife traffickers are quick to adapt in their methods and their trafficking routes, exploiting gaps in regulation and legislation and pouncing on market trends.

Organized criminal groups remain heavily involved in wildlife crime and play important roles across the trafficking chain, from source to end market, while corruption continues to hamper regulation and enforcement efforts, and new technologies provide traffickers with better access to global markets.

Disrupting and dismantling this criminal enterprise requires multifaceted interventions at both the supply and demand ends, including through policy engagement, law enforcement and market suppression. Responses must be agile, targeted, and harmonized, benefitting from robust international cooperation.

It is also important to always keep communities and their wellbeing front and centre. They are the custodians of nature’s treasures, and we must raise their awareness, partner with them, and protect their interests.

To enable such comprehensive responses, interventions must be informed by strong scientific evidence. This report speaks to the growing body of evidence on wildlife crime, just as it speaks to the need to expand this body even further, by investing more in building data and analytical capacity, in researching impacts and risks, and in monitoring developments in illegal wildlife markets.

I hope that this report will generate greater momentum for more effective interventions, more coherent policy commitments, and more attention to the great damage caused by this vast criminal industry.

Review and comments

The World Wildlife Crime Report 2024 benefited from the invaluable contributions by UNODC colleagues in all divisions. Particularly, the support provided by Sinead Brophy, Giovanni Broussard, Hanny Cueva-Beteta, Jenna Dawson-Faber, Leopoldo Fernandez Herce, Nicole Quijano-Evans and Zhiqiang Tao from the UNODC Global Programme on Crimes that Affect the Environment and by Adrianna Collins, Tanya Wyatt and Sonya Yee from the UNODC Research and Trends Analysis Branch is gratefully acknowledged.

The Research and Trend Analysis Branch acknowledges the invaluable contributions and advice provided by members of the World Wildlife Crime Report Scientific Advisory Committee: Debbie Banks, Renata Cao, Hyeon Jeong Kim, Moenieba Isaacs, Pia Jonsson, Andrew Lemieux, Manuel Medina, Jacob Phelps, Cynthia Ratsimbazafy, Scott Robertson, John M. Sellar OBE, Rohit Singh and Xu Ling.

Thanks are also due for inputs into and reviews of case studies: Sharon Baruch-Mordo, Melanie Butler, Dan Challenger, Jenny Feltham, Sarah Foster, Chris Morris and Dan Stiles.
Research for this Report benefited from the expertise and invaluable contribution by the Secretariat of the Convention on International Trade in Endangered Species of Wild Fauna and Flora (CITES). Also, other partner members of the International Consortium on Combating Wildlife Crime (ICCWC), the International Criminal Police Organization (INTERPOL), the World Bank and the World Customs Organization (WCO), supported the development of the report. Input was also provided by the United National Environment Programme (UNEP).

All Member States that supported UNODC field research in their country are also gratefully acknowledged.

The preparation of this report benefited from the financial contributions of Germany, the United Kingdom and the United States of America.
1. Wildlife trafficking persists worldwide despite two decades of concerted action at international and national levels—more rapid and measurable progress could be achieved if interventions were informed by stronger scientific evidence.

2. With thousands of wildlife species affected and a diverse range of distinct markets driving multiple environmental and societal harms, interventions to reduce wildlife trafficking need to be prioritized and more strategic.

3. Corruption undermines regulation and enforcement while technology accelerates the capacity of traffickers to reach global markets—criminal justice responses should be modernized, strengthened and harmonized from source to end markets.

4. Wildlife crime is interconnected with the activities of large and powerful organized crime groups operating in some of the most fragile and diverse ecosystems from the Amazon to the Golden Triangle—addressing wildlife trafficking in these circumstances requires a broader strategy to address organized crime as a whole.
Key Messages

Wildlife trafficking persists worldwide despite two decades of concerted action at international and national levels—more rapid and measurable progress could be achieved if interventions were informed by stronger scientific evidence.

» There are signs of progress in reducing the impacts of trafficking for some iconic species, elephants and rhinoceros, but UNODC’s assessment of available evidence gives no confidence that wildlife trafficking overall is being substantially reduced.

» Lessons from where progress is being made indicate that multifaceted interventions at both demand and supply stages can reduce wildlife trafficking. While success is often measured in terms of arrests and seizures, these measures alone do not necessarily have long-term impact in reducing the criminal incentives that drive illicit markets.

» Wildlife traffickers are adaptable, adjusting their methods and routes in response to regulatory changes and to exploit differences between legal regimes, enforcement gaps and new market trends. Interventions to reduce wildlife trafficking need strong coherence and harmonization across the trade chain. Consideration should also be given to the social and economic dynamics affecting the illicit economy of broader sectors rather than single species. This requires strong international cooperation and a solid evidence base to guide design, implementation and evaluation of remedial action.

» Research on what works to address other crime types suggests that wildlife crime responses could be strengthened through better geographic and commodity targeting, predictive responses to species and geographical displacement, criminal behaviour forecasting, and focused deterrence.

» While there is a growing body of evidence around wildlife crime—as shown in the material presented in the current report and the rich scientific literature on wildlife crime—many knowledge gaps persist that limit a full evidence-based approach. More and better investment is needed on building data and analytical capacity at national and international level.

Corruption undermines regulation and enforcement while technology accelerates the capacity of traffickers to reach global markets—criminal justice responses should be modernized, strengthened and harmonized from source to end markets.

» While corruption is known to enable wildlife crime and undermine the criminal justice response, wildlife crime cases are seldom prosecuted through corruption offences. Greater consideration should be given to prosecution of those organizing or enabling wildlife trafficking under laws directly addressing corruption, which may provide stronger investigative powers and potential for higher penalties than applicable under environmental legislation.

» More attention is also warranted to sector-specific corruption vulnerabilities related to specialized public sector roles such as harvest, breeding and trade permit issuance, animal health and phytosanitary inspection, and control of specialized retail outlets.

» Deterring serious criminal engagement requires serious enforcement responses through more incisive investigation of major beneficiaries and targeting enforcement action to undermine the financial motivations for trafficking.
Wildlife crime encompasses a multitude of different actors, species, commodities and driving factors and it has different impact across environmental, social, economic development and governance aspects. No one single perspective, policy or programme can address this multi-faceted crime. Effective responses require the prioritization of concerted efforts at national and international level.

Assessment of the level of harm posed by the different forms of wildlife crime is one lens through which interventions can be prioritized and targeted. Among the 4,000 animal and plant species that are affected by recent wildlife trafficking, there are different risks for overexploitation, ecosystem disruption, and potential impacts on climate stability. Socioeconomic harms are also diversified, reducing the benefits derived from nature, threatening human security, health and livelihoods, and having a corrosive influence on governance and the rule of law.

This wide range of interlinked environmental and societal harms is typically not explicitly recognized; resolving conflicting perspectives on their relative importance could help strengthen the prioritization and pursuit of remedial action.

Another way to target and prioritize interventions is by assessing the diverse factors that drive criminal activity and the different actors operating at various stages of the wildlife trafficking chain, from illegal sourcing to end-market demand. Some communities at source pay the cost of protective regulations as the economic and social benefits of previously legal harvest extraction and trade can vanish, while traffickers continue to enjoy the financial benefits of the illicit economy. Targeted and proportional responses are needed that address specific motivations for involvement in wildlife crime and reduce risks of unintended negative outcomes.

Wildlife crime is interconnected with the activities of large and powerful organized crime groups operating in some of the most fragile and diverse ecosystems from the Amazon to the Golden Triangle—addressing wildlife trafficking in these circumstances requires a broader strategy to address organized crime as a whole.

Convergence of wildlife trafficking operations with other criminal businesses can drive rapid change in market circumstances, through dynamics such as exertion of territorial power, exploitation of corrupt relationships, access to illicit firearms and opportunities for money-laundering. When powerful organized crime groups are engaged in wildlife crime in the context of other larger illicit economies, they amplify the negative impact of wildlife crime on the environment and community.

Organized crime is evident in various specialized wildlife trafficking roles, such as export, import, brokering, storage, keeping and breeding live specimens or handling the interface with processors. Traffickers can also actively manipulate demand in end markets to sustain or expand business opportunities.

Investment in monitoring and analysing new developments in illegal wildlife markets and associated criminality on an ongoing basis is a prerequisite for effective adaptation of wildlife trafficking responses.
Key Figures at a Glance

Diversity of species recorded in seizures
Percentage share of all seizure records by species group 2015–2021

Species most affected
Just 15 broad markets comprised the bulk of the observed illegal wildlife trade during 2015–2021 based on standardized seizure index

* Other Liliales includes agave, snowdrop and yucca species.

* Other Sapindales species include mahogany, holy wood and Guiacum

** Other Myrtales species include ramin and eucalyptus
Commodities in trade
Top commodities by percentage of seizure records 2015–2021

The boundaries and names shown and the designations used on this map do not imply official endorsement or acceptance by the United Nations.
Final boundary between the Republic of Sudan and the Republic of South Sudan has not yet been determined.
Dotted line represents approximately the Line of Control in Jammu and Kashmir agreed upon by India and Pakistan. The final status of Jammu and Kashmir has not yet been agreed upon by the parties.
A dispute exists between the Governments of Argentina and the United Kingdom of Great Britain and Northern Ireland concerning sovereignty over the Falkland Islands (Malvinas).
Certain countries and their territories report separately under CITES. Dots therefore reflect both categories.
Summary conclusions & policy implications

About this report

This third edition of the *World Wildlife Crime Report*, like its predecessors published in 2016 and 2020, probes trends in the illicit trafficking of protected wildlife species. It also presents systematic analyses of wildlife crime harms and impacts, probes the factors driving wildlife trafficking trends, and takes stock of current knowledge about the effectiveness of the different types of intervention being pursued to resolve this problem.

The records of government wildlife seizures that help inform global and thematic analyses in the current report are significantly more comprehensive than was the case for previous UNODC analyses. This is largely due to the availability of national Convention on International Trade in Endangered Species of Wild Fauna and Flora (CITES) Annual Illegal Trade Reports, first submitted in 2016 and accessible through 2021 for the current report. These records, together with supplementary seizure data collated by UNODC from diverse sources and verified with Member States, form the WWCR3 analytical dataset for the current report. It includes over 140,000 records of wildlife seizures reported to have taken place between 2015–2021. In assessing trends over the period 2015–2021, it is notable that the annual number of seizures reported for 2020 and 2021 was around half the number reported for each of the preceding four years. It is not possible to be sure to what extent this reflects reduced reporting, less enforcement action, a genuine reduction in trafficking levels, or shifts to new modes of marketing and moving illegal wildlife shipments more likely to avoid detection. As discussed below, any of these factors could have been attributed to COVID-19 pandemic disruptions. Such data in any
Sometimes a seizure may include information on the alleged country of departure and/or destination of a shipment, which may provide greater insight into the trade route involved. Triangulation with other records may give some indication whether the country of seizure was the actual origin, a point of transit or an end market.

Seizures may take place anywhere along the trade route.

case cannot provide a full representation of illegal wildlife trade over this period because there are geographical gaps in seizure recording, a strong focus on species listed in the CITES Appendices, and an unknown volume of illegal trade that evades enforcement interventions.

Understanding wildlife crime through seizures and other indicators

Since seizure data can provide only a partial picture of actual wildlife trafficking flows and trends, the current report also draws from a wide variety of additional sources. These include results of new fieldwork by UNODC examining specific wildlife trafficking challenges, supplementary market data, new studies developed in response to CITES decisions, and review of growing academic literature in this field. It also benefits from consultation with a wide range of experts working on related topics. Triangulation of these different sources helps to reveal important insights into the scope and scale of global wildlife trafficking.
Wildlife trafficking continues as a worldwide concern

Findings

The diversity and geographical scope of wildlife trafficking remain enormous

Analysis in the current report demonstrates that the global scope and overall scale of wildlife trafficking remain substantial. Seizures document illegal trade in 162 countries and territories during 2015–2021 affecting around 4,000 plant and animal species, approximately 3,250 of them listed in the CITES Appendices. As a crude depiction of scale, these seizures involved 13 million items reported by number and over 16,000 tons reported by weight during these seven years. This illegal trade flows into a wide range of end use sectors, including food, medicine, live animal and plant keeping, and “luxury” goods. Actual wildlife trafficking levels are of course far greater than the recorded seizures and it is important to keep in mind that there are important gaps in seizure-based evidence of trafficking in timber, fisheries and some other large trade sectors.

Progress to meet the SDG target to end wildlife trafficking is not on track

For the first time in 2024, UNODC has populated an indicator on progress towards target 15.7 to end trafficking of protected species of flora and fauna under the framework of the Sustainable Development Goals (SDGs). An initial estimate of the indicator trend for 2016–2021 suggests that globally the intercepted illegal wildlife trade as a proportion of all wildlife trade (legal and illegal) increased from 2017 onwards, reaching its highest levels during the COVID-19 pandemic in 2020 and 2021, when wildlife seizures made up around 1.4–1.9 per cent of global wildlife trade. For comparison, this proportion had varied between 0.5–1.1 per cent during the previous four years. These estimates give no reason for confidence that SDG target 15.7 is on track to be met by 2030.

The COVID-19 pandemic partly reshaped but did not stop wildlife trafficking

Understanding the full impact of the economic and social upheavals of the global COVID-19 pandemic on wildlife trafficking remains challenging. It is clear from seizure trends and contextual information that there was a very large reduction in wildlife trafficking from personal baggage in air transport in 2020 and 2021 owing to restrictions on the movement of people in many countries and a massive fall in air passenger numbers. However, the impact of other possible influences of the pandemic on seizure trends, for example market restrictions, different consumer choices, changes in enforcement effort, and interruption of official reporting, require more careful interpretation. Annual wildlife seizure numbers were lower in 2020 and 2021 than in earlier years, but trends in seizure volumes and aggregated measures were not consistently downwards. For comparison, the interception of other illegal markets during the pandemic was also inconsistent. The number of detected victims of trafficking in persons decreased during the pandemic, while the levels of drug seizures did not show a similar decline.

Signs of progress for some wildlife commodities

Elephant ivory and rhinoceros horn trafficking are two examples for which the opportunity to triangulate data on illegal trade, illegal harvest and species population...
Summary, conclusions & policy implications

Trends in the proportion of wildlife trade represented by seizures based on aggregated indices of legal trade and seizures 2016–2021 (SDG indicator on progress towards target 15.7 to end trafficking in protected species)

Change are far stronger than is typical. Both have been subjects of case studies in past editions of the World Wildlife Crime Report and are revisited again in the current edition. The latest analyses provide grounds for some optimism that a combination of efforts from both demand and supply side with high-profile policy attention, greater market restrictions and targeting of high-level traffickers with law enforcement action may be returning positive results. Over the past decade, poaching, seizure levels and market prices have declined solidly for both commodities. However, sporadic large seizures of both elephant ivory and rhinoceros horn continue to occur and these markets have experienced significant declines and revivals in the past, so continued vigilance is warranted. Although far from resolved and requiring ongoing scrutiny, these examples do however demonstrate that substantial progress can be made.

Increased national, regional and international action to combat wildlife crime

Wildlife seizure records are not simply an indicator of trafficking flows, they also demonstrate that enforcement action has been taken. Although there are no reliable measures to assess if and to what extent enforcement and other actions have reduced wildlife trafficking, there are good indications that there has been a substantial increase of these actions globally over the past two decades. The evolution of regional wildlife enforcement networks since the late 1990s, the establishment of the International Consortium on Combating Wildlife Crime (ICCWC) in 2010, the series of four international illegal wildlife trade conferences held between 2014–2018, and the adoption of six United Nations General Assembly resolutions on this subject between 2015–2023, all reflect the growth
in practical and policy attention. Many key countries have created specialized enforcement units, multi-agency teams and national strategies, and have recognized wildlife crime as a priority crime. A forthcoming UNODC legislation analysis indicates that 164 Member States of the United Nations criminalize wildlife trafficking violations to some degree, with 86 of them having penalties that meet the United Nations Convention against Transnational Organized Crime (UNTOC) definition of a serious crime with a maximum custodial penalty of at least four years. This is the highest level of criminalization across nine environmental crime sectors analysed. In addition, a series of coordinated multi-country counter wildlife trafficking operations have also been carried out since the early 2010s, including three iterations of the multilateral Operation Cobra initiatives between 2013–2015, and the seven Operation Thunder initiatives during 2017–2023. Regional initiatives include the five phases of Operation Mekong Dragon during the period 2019–2023, multilateral Asia regional law enforcement pushes targeting both narcotics and wildlife smuggling. Also, considerable progress has been made with engagement of private sector businesses in efforts to increase barriers to trade-related wildlife crime, including through task forces for the financial and transport sectors.

**Challenges in determining the impact of action on wildlife crime**

Discerning the impacts of increased attention to and action on wildlife trafficking and associated crime is far from straightforward. If such efforts were successful, illegal trade flows would be expected to decrease, the pressure of illegal harvests would be relieved, and positive wildlife population trends would be realized. However, each of these indicators of success is difficult to discern individually and the chain of cause and effect is complicated. Global analysis of seizure data may provide some insight into the question of whether illegal trade flows have declined if they are triangulated with associated price and market observations. Demonstration of a
reduction in illegal harvests is more challenging because relevant data are not collected for the vast majority of species subject to wildlife trafficking. Similarly, changes in wildlife population levels are not systematically monitored for most affected species. Even where positive trends can be discerned, it is important to pay attention to the risk that traffickers have moved on to deal in other wildlife commodities under less enforcement and market pressure. Indeed, case studies in the current report demonstrate the establishment of linkages between ivory and pangolin illegal trade chains and other examples of traffickers shifting attention between different species and source countries.

Conclusions and policy implications

- Despite gaps in knowledge about the full extent of wildlife trafficking and associated crime, there is sufficient evidence to conclude that this remains a significant global problem far from being resolved.

- Continued commitment to pursue incisive and coordinated action on trade-related wildlife crime is essential. Remedial approaches championed in previous editions of the World Wildlife Crime Report remain relevant, including calls for increased local community engagement; investigative follow-up to seizure incidents; action to address corruption; prosecutorial support; consumer demand reduction initiatives; inter-agency coordination at the national level; and international cooperation on criminal matters.

- The apparent progress with reductions in poaching and illegal trade in elephant ivory and rhinoceros horn over the past decade suggests that multifaceted interventions through policy engagement, law enforcement and market suppression can reap rewards.

- Important lessons can be derived from these examples about the scale and depth of action required to impact persistent criminal trafficking chains. Major seizures have resulted from multilateral investigations, prosecutions of key traffickers have been pursued and, over time, legal prohibitions have been harmonized across the trade chain from source to end markets. These cases also demonstrate the benefits of investment in tracking impact indicators in order to assess the impact of different interventions.

- The diversity of institutions and intensity of initiatives working to reduce wildlife trafficking have increased substantially over the past decade, but to make the most of this effort there is a need for more structured coordination between government and multilateral agencies, civil society organizations, academics and the private sector.
Wildlife crime harms are diverse and pervasive; their understanding can support better prioritization of action

**Findings**

**Thousands of threatened wildlife species are affected by wildlife trafficking and some of those worst affected receive little public attention**

The impact of wildlife trafficking on the conservation status of wildlife species is a critical concern driving policy attention to wildlife crime. A review of evidence about harms caused by wildlife crime in the current report makes it clear that thousands of threatened species are affected by wildlife trafficking, a small minority of which, such as elephants, tigers and rhinoceros, attract the majority of policy attention. In fact, some of the clearest examples of conservation harm caused by wildlife crime receive comparatively little attention, such as the illegal collection of succulent plants and rare orchids, and the trafficking of a wide range of reptiles, fish, birds, and mammals for which illegal trade appears to have played a major role in local or global extinctions.

**Beyond the threat to individual species, wildlife trafficking harms ecosystems and their climate-related functions**

On environmental harms beyond the immediate conservation threat to target species, population reductions caused by wildlife trafficking can play a role in triggering ecosystem-level impacts by disturbing interdependencies between different species and undermining related functions and processes. This also has considerable potential to undermine the role that natural ecosystems play in long-term climate stability and mitigation of climate change impacts.

**Wildlife crime harms socioeconomic development**

Species depletion and ecosystem disruption caused by wildlife crime can undermine the many socioeconomic benefits that people derive from nature. This includes loss of employment and other income from wildlife-based industries and degradation of the material benefits that nature provides to people, such as food, medicines and energy, as well as non-material contributions to identity, culture and learning. Wildlife trafficking can also undermine the role nature plays in life support systems such as agriculture and water supply. Impacts of wildlife crime can extend to reduced security, exposure to violence, undermining community cohesion, and increased vulnerability to abusive employment practices and trafficking in persons. Other potential social and economic impacts include harm to environmental defenders, increased health risks through disease transmission and negative effects on legitimate private sector interests.

**Governance is also impacted by wildlife crime**

Wildlife trafficking can also have a corrosive influence on governance and the rule of law through corruption, money-laundering and illegal cross-border financial flows. It can also reduce government revenues from legitimate trade, such as licence fees from legal timber harvest and export, and other uses of nature, such as taxation from tourism business. Tackling wildlife trafficking has significant associated government budget costs.

**Responses to wildlife crime can themselves be harmful if not well designed**

Some harms result from responses to wildlife crime that do not effectively target the core of the problem. For example, criminal justice responses that result in incarceration of lower-level participants in wildlife trafficking can have significant socioeconomic consequences that may not be proportionate to the role such people may have played in comparison to
higher-level participants and those operating across jurisdictions. Although comprehensive data on criminal justice responses are not available, individual studies indicate that low-level offenders tend to be those more likely to be arrested and incarcerated for involvement in wildlife crime. There is a risk that this creates an illusion of progress, with counts of seizures and arrests being poor indicators of the likely impact overall on levels of trafficking activity. Meanwhile, higher-level criminals simply find new people to front their operations.

Lack of consensus on the importance of different wildlife crime harms can hamper effective responses

Analysis revealed tensions between different perspectives of the harm resulting from wildlife crime. Some of the most dangerous illegal trade flows from a conservation perspective may involve low volume trafficking of highly threatened species, such as rare succulent plants and orchids for which this activity presents a genuine extinction risk. However, the monetary value and the immediately obvious social and institutional harms associated with such trade are likely small compared with those related to species illegally traded in larger quantities. Conversely, lucrative criminality and multiple harms may result from trafficking of species still perceived as relatively plentiful, albeit subject to regulatory control of harvest and trade, such as those exploited in high-value fisheries and timber trades. Dissonance between these different perspectives on wildlife crime harms can challenge prioritization and pursuit of remedial action.

Conclusions and policy implications

- The case for action on wildlife crime would be strengthened by better articulation and quantification of how associated harms are linked to high-level policy concerns, such as climate, biodiversity, health and sustainable development goals.
Wildlife crime harms

- Greater attention should be paid to improving understanding of the interdependence between environmental, socioeconomic and governance factors in order to strengthen assessment of and responses to the harms of wildlife trafficking. For example, through further research on ecosystem and climate impacts, or on the specific health-related risks of illegal trade.

- Greater efforts are required to unite different perspectives on wildlife crime harms at a policy level.

- At a tactical level, there is a need for more comprehensive accounting for the cascade of interlinked environmental, socioeconomic and governance harms in wildlife crime risk assessment, with prioritization of remedial interventions.

- To enable such accounting, there is a strong need to improve the evidence base and articulation of indicators of risk and severity (such as risk factors for zoonotic disease and a clearer measure of conservation significance of seizures) for all types of harm arising from wildlife trafficking.

- Design of wildlife crime prevention and reduction strategies would benefit from the use of hybrid indicators that combine measures of different harms. Consideration of these may lead to the emergence of new priorities in terms of species, commodity types and geographies.

- The proportionality of criminal justice responses should be carefully considered to ensure that the greatest enforcement effort and most severe sanctions are directed to those playing the most serious and harmful roles in organized wildlife crime.

Environmental Harms
- Species overexploitation
- Ecosystem impact
- Climate impacts
- Dispersal of invasive species

Social and Economic Harms
- Livelihoods and well-being
- Business costs and losses
- Health risks
- Harm to defenders

Governance Harms
- Undermining the role of governments
- Loss of government revenues
- Enforcement costs
The forces driving wildlife crime are diverse, complex and evolving

Findings

Different factors drive criminality associated with wildlife trafficking at different stages of the trade chain: illegal sourcing, illegal trade, and demand in end markets. Financial gain from the profits of wildlife trafficking is a primary motivation for most participants in illegal sourcing and trade, but the context by which they become involved defines the scale and critical drive of their involvement.

Organized crime groups continue to profit from large wildlife trafficking operations

Case study research and other sources confirm that organized crime remains a significant factor in many illegal wildlife sourcing and trading chains. At source, professional remotely directed gangs have been active in elephant and tiger poaching, and industrial scale illegal fishing and logging operations are well documented. Sometimes convergence with other criminal businesses enables wildlife trafficking through power relationships with local communities, corrupt relationships, access to illicit firearms and opportunities for money-laundering. Along the trade chain, organized crime is evident in various specialized roles, such as export, import, brokering, storage, keeping and breeding live specimens or handling the interface with processors. There is evidence, for example from the rhinoceros horn trade, that traffickers can play an active role in manipulating demand in end markets to sustain or expand business opportunities.

Some participants in the trafficking chain are opportunists driven by basic needs for income

Organized criminal groups may play central roles in orchestrating the illegal sourcing of some commodities, but those doing the legwork may be opportunists, motivated by basic needs for income with limited understanding of the potential consequences of their actions. They may be particularly vulnerable when regulatory change criminalizes what were previously legal activities and reduces immediate economic opportunities. Furthermore, involvement in poaching of some animal species may result from human—wildlife conflict, such as damage to crops by elephants or predation of livestock by big cats.

Traffickers exploit inconsistencies and weaknesses in regulation and enforcement

Participants along the illegal wildlife trade chain tend to adapt the methods and routes they employ to shifts in the regulatory and enforcement landscape for different commodities. For some commodities the full trade chain from source to end market operates in contravention of applicable legislation, but for others illegally sourced and traded goods can enter what may appear to be legal trade flows. This can happen when goods are laundered through ostensibly legal stockpiles or breeding operations but may also be because legislation applicable in the end market does not provide jurisdiction over illegal acts outside its territory. For example, timber harvested illegally may be infiltrated into the legal trade chain, then used to manufacture furniture and sold in another country where, even if a crime occurred at the source, there is no legal basis for intervention. However, traffickers exploit not only legislative inconsistencies but also weak law enforcement capacity. Several case studies in the current report show that, even when there is political will, the agencies responsible for implementation and enforcement of wildlife trade regulations may lack the capacity and resources they need to perform effectively.

Wildlife trafficking involves diverse demand clusters with different market drivers; traffickers adapt to and sometimes shape evolving markets to maximise their opportunities for profit

The characteristics of predominant demand clusters for species affected by wildlife trafficking result from different market drivers. For example, products used for food and medicinal uses are typically sought in bulk quantities that meet a particular quality requirement. If the same standard can be maintained, traffickers simply move to alternative species or localities as supplies become scarce to continue to meet the bulk demand. By contrast, for demand sectors in which rarity and exclusivity are key consumer
motivations, such as specialist live animal and plant collectors and status-conscious consumers of ivory or big cat skins, scarcity may simply attract more trafficking. In some cases, illegal traders appear to play an active role in shaping end market opportunities, promoting new use types to sustain or grow sales when existing uses lose popularity with consumers or face increased regulatory pressure.

Gender is a factor that shapes roles of people involved in wildlife trafficking

Across the trade chain from source to end market there are important gender-related drivers of involvement in wildlife crime. Research in South America for the current report illustrates how gender norms and roles shape individuals’ participation in wildlife-based economies, both legal and illegal. Influencing factors include different experiences of and access to wildlife, expectations within familial structures, and established role differentiation. In locations surveyed, women played prominent roles in primary processing and local sale of wildlife goods typically harvested by men. Involvement in wildlife crime exposed men and women to different risks, including exploitative practices and violence.

Corruption plays a critical role in undermining efforts to disrupt and deter wildlife trafficking

As highlighted in previous editions of the World Wildlife Crime Report, corruption plays a critical role in undermining efforts to disrupt and deter wildlife trafficking. This varies from bribery at inspection...
Establishment, maintenance, and breakdown of corrupt relationships that facilitate transnational illegal wildlife trade

Conclusions and policy implications

- Actions to address wildlife trafficking would likely be more effective if planned and implemented as integrated components of wider strategies to resolve overexploitation of species and other related harms for distinct wildlife trade sectors, such as the rosewood or live reptile markets. The entry of criminal activity into such markets is a predictable by-product of piecemeal regulatory interventions within sectors with common supply and demand drivers. The risks of crime and possible responses should be factored into regulatory planning.

- If remedial interventions are to be successful, greater attention is needed on the complexity and
diversity of motivations for those involved in wildlife trafficking at different stages of the chain from source to end market. Gender dimensions of wildlife trafficking drivers and responses are also among the factors that require attention.

- Action on illegal sourcing needs to be designed with attention to the fact that profit-related motives may not always predominate, with basic livelihood imperatives and other social and cultural factors that could also be relevant. For example, prevention or mitigation of human–wildlife conflict can play a critical role in reducing poaching motivations for some species for which local communities may feel they are bearing too great a share of conservation costs.

- If regulatory interventions related to wildlife harvest and trade are likely to cause loss of economic opportunities for people with limited livelihood alternatives, compensation, or other pre-emptive actions should be considered to reduce the likelihood that they become involved in wildlife crime.

- Deterring serious criminal engagement requires serious enforcement responses through more incisive investigation of major beneficiaries and targeting enforcement action to undermine the financial motivations for trafficking.

- Interventions aimed to reduce wildlife trafficking need greater coherence and harmonization across the trade chain and between jurisdictions because there are currently too many opportunities for participants to keep adapting their methods and routes to exploit differences between legal regimes, enforcement gaps and new market trends.

- A starting point to reduce opportunities for trafficked wildlife to enter legal trade in other jurisdictions is to require stronger proof of legal sourcing for imports of wildlife goods, as provided for under CITES for listed species and, for example, under European Union law applicable to timber trade. Where legal systems allow, another opportunity to strengthen coherence of legal measures between jurisdictions is the enactment of provisions that designate the contravention of any applicable law concerning the protection or management of wildlife in another country as an offence, such as those applicable under laws in Australia and the United States of America.

- To reduce opportunities for laundering trafficked wildlife goods into legal trade chains further, consideration could be given to widening the range of wildlife trade-related activities that are subject to legal control, for example by complementing controls on harvest or cross-border movement of wildlife goods with regulatory oversight of acts such as the offer for sale, purchase or possession.

- There is a need for improved control of breeding operations and stockpile inventories for species subject to wildlife trafficking to reduce opportunities for laundering.

- Although some of the corruption challenges undermining action to address wildlife trafficking are not unique to this sector and require system-wide responses, more attention is warranted for sector-specific vulnerabilities. Of particular importance is the need to build robust corruption risk responses for specialized public sector roles such as harvest, breeding and trade permit issuance, animal health and phytosanitary inspection, and control of specialized retail outlets.

- Strengthening the basic capacity of agencies responsible for wildlife trade regulation and related law enforcement remains a critical priority for both deterrence and suppression of wildlife crime.
Counter wildlife trafficking interventions lack guiding evidence

Findings

There are clear advantages to be gained from enhancement of evidence about what measures are effective to address wildlife crime. Such knowledge can be used to prioritize, target, evaluate and refine wildlife crime interventions, employing the wide range of analytical and planning tools already in use in the wider crime prevention community. Such evidence would enable better assessment of the value of capacity and resource allocations and inform decisions about investment of scarce resources.

While evidence on effective interventions is weak, there are some lessons to be learnt

Analysis of available evidence on the effectiveness of different counter wildlife trafficking approaches reveals remarkably few published systematic assessments that draw a clear comparison between the situation before and after remedial interventions are made. Success is typically judged based on outcomes such as seizures, arrests and prosecutions, rather than through assessment of changes in crime levels, illegal trade volumes or relief of associated harms, like recovery of threatened species populations. Even when potentially informative impact data are available, such as on population levels of affected species, the level of resolution and other factors undermine their utility in establishing causal inks to specific wildlife crime interventions.

Despite important evidence gaps, there is a growing body of research on the effectiveness of different wildlife crime responses and useful insights are emerging

Effective patrolling

Evidence-based analysis illustrates that the impact of anti-poaching patrolling in certain locations depends on particular circumstances: the habitat’s accessibility; rangers’ level of experience and numbers; the time spent patrolling; the longevity of patrols; the type of patrol conducted; the type of target and its mobility; and the bonus/incentives provided to patrollers.

Multi-track interventions

Review of wildlife trafficking case study examples suggests that more successful approaches include sets of mutually supporting interventions such as those that block opportunities, those that increase risks for criminal participants, and those that reduce rewards from crime.

Responses that involve both supply and demand

Multifaceted enforcement and market interventions have contributed to reductions in ivory trafficking and elephant poaching showing that effective responses likely need to involve both supply and demand side interventions.

Lessons can be drawn from evidence-based approaches in other crime sectors

Learning from research into other crime sectors may help with identification of remedial approaches that might have positive impacts in dealing with wildlife trafficking. Examples include geographic and commodity targeting, criminal behaviour forecasting, focused deterrence, and use of restorative justice approaches. Similarly, such research provides useful insights into crime displacement and avoidance of unintended and unhelpful consequences, such as social harms that sustain rather than deter crime motivations. Substantial guidance is already available on how such approaches could be applied more effectively to address wildlife trafficking.

Wildlife crime data resources are inadequate for effective impact assessment

The most significant challenge to accumulation and use of evidence to assess effective responses is the lack of investment in monitoring and evaluation processes, including indicator development, data collection and structured assessment. Within relevant government systems, priority is usually given to direct operational intervention, with limited attention to collection and evaluation of associated crime data.
Evidence reviews indicate that data sources on wildlife crime are currently rather limited in terms of scope and accessibility compared to those available for other crime sectors for which policing results, crime perception and other surveys are available to researchers and the public in many jurisdictions. National datasets on wildlife crime are, in contrast, fragmented, short-term and difficult to access, with a bias towards information on seizures, particularly of illegal shipments of CITES-listed species. Information on enforcement effort, prosecutions, convictions, sentencing, reoffending and differentiation of data by gender or other factors is absent or very difficult to locate.

**Conclusions and policy implications**

- Improved approaches to assess what measures are effective need to focus on two levels of evidence and evaluation, the direct process-related results of interventions and the consequent impact on crime levels and associated harms. This will require greater cooperation between different communities of research and practice, including those involved in conservation and socioeconomic assessments, law enforcement and market analysis.

- A greater emphasis on collation and analysis of evidence on the results from wildlife trafficking responses is needed to guide decisions by policy makers, regulatory and enforcement agencies and funding agencies in deciding which remedial interventions to fund and implement in different circumstances.

- Action is needed to enhance the quality and coverage of wildlife seizure data, both geographically and in terms of species involved. This requires greater prioritization of seizure data collation and submission by individual government agencies, accompanied by capacity building and other support. Although the highest priority is to improve submissions of CITES Annual Illegal Trade Reports, systematic collation and sharing of seizure data for species not covered by CITES is also important.

- Seizures alone cannot confirm trends and characteristics of wildlife trafficking and other data types are needed, for example on levels of demand, commodity prices, retail availability and turnover, and metrics on criminal justice outcomes. Better knowledge is also needed about changes in different measures of environmental, socioeconomic and governance harm, and clearer differentiation by gender and other relevant factors.

- Collation and analysis of evidence could be enhanced by development and dissemination of data standards for different metrics and efforts to improve data interoperability and sharing.

- When relevant, data sources should be disaggregated by gender and other characteristics that might aid understanding of specific motivations for different participants in wildlife crime.

- Funding agencies are in a strong position to provide greater incentives and support for collection, sharing and analysis of evidence about the performance and impact of wildlife crime interventions. This cannot be achieved only through project activity monitoring and evaluation as it also requires investment in dedicated longer-term evidence and data collection and analysis.

- Improved analysis of emerging wildlife trafficking issues and trends will benefit from greater emphasis on triangulation between these different sources of evidence. Communities of practice for sharing both evidence and learning could greatly boost evaluation and refinement of wildlife crime interventions overall.

- Emerging evidence on successful wildlife crime responses and learning from research into what works in dealing with other crime sectors should be put to immediate use to refine responses to wildlife trafficking.
Wildlife crime operational interventions

At source
- Reducing and mitigating human-wildlife conflict
- Supporting legal livelihood options
- Reducing incidental take
- Guarding by law enforcement or private and community rangers
- Reducing availability of and removing snares and weapons
- Area access controls
- Local surveillance and intelligence gathering

In trade
- Warning to traders and travellers
- Inspection of commercial breeding operations
- Stockpile and inventory control
- Inspection and control at border and market hubs
- Identifying falsified documentation
- Pinpointing corruption
- Building safeguards in supporting businesses to reduce facilitation
- Intelligence gathering on crime networks

End market
- Possession controls and inspections
- Consumer behaviour change communications
- Enabling access to legal, traceable alternative supplies
- Promoting substitutes

Delivering justice
- Confiscation and other immediate sanctions
- Arrest
- Prosecution
- Conviction and penalties (financial and imprisonment)
- Asset recovery
- Rehabilitation of offenders

Shaping the Enabling Environment
- Strengthening treaties and national laws
- Catalysing international and inter-agency cooperation
- Building capacity of implementing institutions and personnel
- Strengthening the wider criminal justice system
- Building general awareness of harms and impacts
- Researching, evaluating and guiding adaptation of wildlife crime responses
Looking ahead

Analysis in the current report demonstrates that wildlife trafficking is a persistent and ongoing global problem. Criminality continues to undermine the impact of laws aimed to reduce harm to nature from excessive trade in wildlife and causes a wide range of associated environmental, socioeconomic and governance harms. However, the current report also provides grounds for optimism. Some persistent wildlife trafficking sectors do appear to have been suppressed in recent years by multifaceted interventions. Although there is no room for complacency, any such progress warrants careful reflection to draw wider lessons about how the challenge of wildlife trafficking might best be met in the future.

New emphasis in this third edition of the World Wildlife Crime Report has been placed on assessment of the causes and impacts of wildlife trafficking and associated crime at a global level. Findings reinforce a critical message that the specific factors driving trafficking from source to end markets vary enormously between different illicit wildlife commodity sectors. Solutions therefore need to be tailored appropriately and there is great potential for ongoing wildlife crime research to assist these efforts by gaining insights into criminal structures, financial incentives, evolving demand patterns, and other diagnostic features of sectorial trafficking chains. Similarly, insights in the current report into the nature of and connectivity between different environmental, socioeconomic and governance harms clarify the need for more comprehensive indicators to enable prioritization and evaluation of the success of future actions.

Finally, by probing evidence for what remedial interventions work best to reduce wildlife trafficking and associated criminality, the current report sheds light on major gaps in current knowledge. Looking ahead there is a clear need for comprehensive consideration of data and analytical needs to fill this void. Possibly even more important is the message that the concept of success in tackling wildlife trafficking needs unambiguous definition. Seizures, arrests, successful delivery of behaviour change campaigns and other interventions may all be positive outcomes, but without some insight into whether they are delivering long-term benefits to the wildlife species, people and institutions currently negatively impacted by wildlife crime, they may not be achieving their intended aims.
Endnotes

1 The number of CITES Annual Illegal Trade Reports received per year remained steady through 2016–2020 and was reduced by only about 10 per cent in 2021.

2 CITES Appendix I includes species threatened with extinction. Trade in specimens of these species is permitted only in exceptional circumstances. CITES Appendix II includes species not necessarily threatened with extinction, but in which trade must be controlled in order to avoid utilization incompatible with their survival. CITES Appendix III includes species that are protected in at least one country, which has asked other CITES Parties for assistance in controlling the trade.

4 Records of legal trade and seizures were each aggregated using a standardized index of relative value. The scope of the indicator is currently restricted to legal trade and seizures of species listed in the CITES Appendices since data for other species are not available at the same level of resolution. See the methodological annex to this report.

This third edition of the World Wildlife Crime Report probes recent trends in the illicit trafficking of protected species of wild fauna and flora and provides a broad assessment of current knowledge about the causes and implications of associated crime at a global level.

As with the first two editions, published in 2016 and 2020 respectively, research carried out for this report included quantitative market assessment and a series of in-depth case studies. The findings inform an overview of recent characteristics and trends in global wildlife crime and provide insights into the dynamics of how it is affecting selected wildlife species. Additional emphasis for this edition is on systematic analysis of wildlife crime harms and impacts, factors driving crime trends, and the evidence for what remedial interventions work best.

The report was prepared in response to the United Nations General Assembly Resolution on Tackling Illegal Trafficking in Wildlife adopted in 2021. This resolution requested the United Nations Office on Drugs and Crime (UNODC), in close cooperation and in collaboration with Member States, to continue and strengthen the collection of information on patterns and flows of illicit trafficking in wildlife.

With the support of
The International Consortium on Combating Wildlife Crime (ICCWC)
Chapter 1
Introduction
This third edition of the World Wildlife Crime Report probes recent trends in the illicit trafficking of protected species of wild fauna and flora and provides a broad assessment of current knowledge about the causes and implications of associated crime at a global level.

As with the first two editions, published in 2016 and 2020 respectively, research carried out for this report included quantitative market assessment and a series of in-depth case studies. The findings inform an overview of recent characteristics and trends in global wildlife crime and provide insights into the dynamics of how it is affecting selected wildlife species. Additional emphasis for this edition is on systematic analysis of wildlife crime harms and impacts, factors driving crime trends, and the evidence for what remedial interventions work best.

The report was prepared in response to the United Nations General Assembly resolution on Tackling Illegal Trafficking in Wildlife adopted in 2021. This resolution requested the United Nations Office on Drugs and Crime (UNODC), in close cooperation and in collaboration with Member States, to continue and strengthen the collection of information on patterns and flows of illicit trafficking in wildlife and to report thereon biennially.

The report has been prepared in coordination with partners of the International Consortium on Combating Wildlife Crime (ICCWC).
Wildlife crime in a changing world

The second edition of the *World Wildlife Crime Report* was published in May 2020, largely based on data available up to the end of 2018. Since that time the global economy and human societies in general have experienced considerable disruption caused by the coronavirus disease (COVID-19) pandemic. This included restrictions on the movement of and interactions between people, while shifts in business and consumption patterns changed global trade patterns. They also transformed the environment of opportunity and threat within which criminal activities are organized and performed. During the pandemic wildlife crime received special attention owing to claims that wild animal trade may have played a role in the emergence of COVID-19. Despite uncertainty about this theory, the concern put a spotlight on wider concerns that wildlife trade and trafficking could contribute to the spread of zoonotic diseases.

These developments were just coming into focus around the time of publication of the 2020 edition of the *World Wildlife Crime Report* when UNODC identified several potential impacts of the pandemic on wildlife crime. These included the possibility that illicit markets would move even deeper underground to avoid scrutiny related to disease risk management. It was also speculated that there may be greater risks of corruption to avoid health-related market restrictions. Additional considerations included the likelihood of sustained shifts in mode and routing of transportation, particularly due to increased use of parcel shipments, and accelerated development of online trading. It was noted at the time that it was far too early to observe clear trends and changes in wildlife trafficking owing to the pandemic and to some extent this may still be the case now.

Since the 2020 edition of the *World Wildlife Crime Report* there have been some significant developments in international policy and actions that have kept wildlife trafficking in the spotlight.

Global legal framework and response

In May 2022, the United Nations Commission on Crime Prevention and Criminal Justice (CCPCJ) adopted a resolution on Strengthening the International Legal Framework for International Cooperation to Prevent and Combat Illicit Trafficking in Wildlife. The CCPCJ invited Member States to provide UNODC with their views on ways to address any perceived gaps in the current international legal framework to prevent and combat illicit trafficking in wildlife, including the possibility of an additional protocol to the United Nations Convention against Transnational Organized Crime (UNTOC). Furthermore, Member States were invited to share their relevant national legislation, experiences, good practices and challenges in terms of preventing and combatting illicit trafficking in wildlife. An initial compilation of Member States’ responses was made available for the 32nd Session of the CCPCJ in May 2023, and an updated version was presented at the 33rd session in May 2024. These included reports of a wide variety of actions taken and suggestions for further remedial measures, including views on the merits of an additional protocol to UNTOC addressing wildlife crime. Additionally, UNODC submitted a summary report to CCPCJ analysing the 76 responses provided by the Member States.

International wildlife trade regulation

The nineteenth meeting of the Conference of the Parties to the Convention on International Trade in Endangered Species of Wild Fauna and Flora (CITES), which took place in Panama in November 2022, took stock of progress with multilateral efforts to regulate international wildlife trade to ensure it does not threaten the survival of wild animal and plant species. Subjects under consideration included analysis of compliance problems, the impacts of ongoing illegal trade on selected wildlife species including some addressed by case studies in the current report, and efforts to enforce the provisions of the Convention. Decisions were taken to introduce or amend trade restrictions for a number of species.
Introduction

**Gender mainstreaming**

International policy statements related to wildlife crime have adopted greater emphasis on social factors, including attention to gender-related concerns. In 2022, CITES Parties adopted a resolution urging greater efforts to understand how gender issues relate to other factors in legal and illegal international trade in wild species of fauna and flora, with a view to taking these into account when designing responses and interventions. The United Nations General Assembly resolutions on Tackling Illegal Trafficking in Wildlife called upon Member States to ensure the full and effective participation and equal opportunities for leadership of women in the development and implementation of relevant policies and programmes addressing illicit wildlife trafficking.

**Nature conservation policy**

After a four-year consultation and negotiation process, the Kunming-Montreal Global Biodiversity Framework was adopted in December 2022 during the fifteenth meeting of the Conference of the Parties to the Convention on Biological Diversity. The Global Biodiversity Framework, which supports the achievement of the Sustainable Development Goals (SDGs), sets out an ambitious pathway to reach the global vision of a world living in harmony with nature by 2050. This includes a specific ambition set under Global Biodiversity Framework Target 5 to take action to ensure that use, harvesting and trade of wild species is sustainable and safe.

**Pursuing the Sustainable Development Goals**

In September 2023 the midterm review of the implementation of the SDGs took place at a summit in New York. A UNODC review of crime-related indicators under SDG goal 16, through which countries aspire to establish more peaceful, just and inclusive societies, concluded that progress is worryingly slow and called for recognition that the current pace of change is insufficient to address some of the most significant challenges relating to violence, trafficking, access to justice, and corruption.

**Mobilizing global enforcement efforts**

Global wildlife crime enforcement efforts continue to be mobilized through Operation Thunder joint initiatives coordinated annually by INTERPOL and the World Customs Organization with the backing of International Consortium on Combating Wildlife Crime (ICCWC) partners. The most recent month-long operation in October 2023 involved police, customs, border control, environment, wildlife and forestry officials in 133 countries, with over 2,000 seizures resulting.

**Quantitative market assessment**

The quantitative analysis in this third edition of the *World Wildlife Crime Report* draws from two complementary sources of data on wildlife seizures made by government enforcement authorities: the CITES Illegal Trade Database; and the UNODC World Wildlife Seizure Database (World WISE). Hereafter this is referred to as the “WWCR3 analytical dataset”.

**The CITES Illegal Trade Database**

This database incorporates seizure records submitted by designated government focal points to the CITES Secretariat under the terms of a CITES resolution on national reporting. Each CITES Party is required to submit an Annual Illegal Trade Report (AITR) on all seizures for violations involving CITES-listed species irrespective of whether the seizure was made at an international border or at a domestic level, for example during the search of a private or business property or during inspections at domestic markets. The database is managed by UNODC on behalf of the CITES Secretariat. Submission of AITRs is mandatory but not subject to compliance procedures. The first year for which such reports were required was 2016 and the extent of submission up to 2021 is illustrated in Map 1.
### The UNODC World Wildlife Seizure Database

World WISE was originally developed to inform quantitative market assessment for the first edition of the *World Wildlife Crime Report*, published in 2016 before the introduction of CITES AITRs. Data compilation at that time drew from a wide range of sources including: World Customs Organization seizure records; the former CITES Biennial Reports and other CITES-related sources; and national records such as those from the United States Fish and Wildlife Service (USFWS) Law Enforcement Management Information System (LEMIS), the European Union Trade in Wildlife Information eXchange (EU-TWIX), and the ASEAN Wildlife Enforcement Network (ASEAN-WEN) databases. After 2016, World WISE data collection has focused on collating records from sources that supplement the CITES Illegal Trade Database, including those filling geographic gaps in CITES data submissions. UNODC employs a range of methods to verify such records and avoid duplication that could result from use of data from multiple sources. As with earlier editions, sources and details of data handling procedures are provided in the methodological annex to this report.

At the time of writing, the CITES and UNODC databases included approximately 336,000 records of seizures from 1999–2021 (Figure 1.1). As is usual practice for UNODC research reports, all data were circulated to Member States for verification in September 2023 and reviewed in line with feedback received.

Most of the analysis in this report was based on data from 2015–2021, which includes over 140,000 records of seizures reported to have taken place in 162 countries and territories. Reported seizures for this period in the two databases involved illegal trade in around 4,000 wildlife species, approximately 3,250 of them species listed in the CITES Appendices. Approximately 1,000 additional World WISE records for 2022 were included in the WWCR3 analytical dataset because...
they help inform preliminary insights into recent developments for species included in some of the case studies.

Seizure data represent a powerful source of information for analysis of wildlife crime, providing insights into the species and commodities in illegal trade, volumes and routing of trade flows, and indications of other factors that shed light on crime patterns, such as means of transport and concealment. Supplementary data provided with many seizure records also provide insights into seizure locations, the reason for seizure, seizing agency, and applicable legislation.

However, in interpreting seizure data it is critical to keep in mind that incidents are as much a representation of the enforcement action taken as they are evidence of the occurrence of illegal trade itself. An absence of seizures of a particular commodity or at a certain location could reflect lack of enforcement, rather than evidence that illegal trade was not taking place. Similarly, the fact that a seizure was made shows first and foremost that an agency in a particular country had the legal authority, capacity and motivation to make an enforcement intervention. The goods involved may have passed through or been destined for other countries and the incident may or may not be indicative of a larger flow of illegal trade.

Analysis of seizure data also needs to be cognisant of reporting biases, both in terms of geographical gaps in data provision and availability, and in terms of the commodities involved. Generally, reporting is weaker for illegal trade involving plant and aquatic species than it is for trade involving terrestrial animals. This may be a consequence of a variety of factors, including the division of responsibility for different commodities between specialized government agencies, varying levels of familiarity with or technical capacity to identify different species, or simply a matter of enforcement prioritization. Other potential biases in terms of geographical representativeness are that enforcement effort may be concentrated at certain locations, particularly at international border crossings and transport hubs.

It is also important to bear in mind that details of individual wildlife seizure records are often incomplete because important information such as accurate species identification, origin of goods, and trade routing is not available to the agency reporting the event. Some seizures are made at storage locations, breeding facilities or markets, rather than during shipment of goods. In such cases, past and intended trade routing may genuinely be unknown. However, even for the large proportion of seizures made during shipment, routing information is often incomplete. Partial reporting of shipment routing is particularly challenging because it limits insights into illegal wildlife trade flows from points of origin, where animals or plants were taken from nature or bred in captivity, to end market countries (Figure 1.2). Trade flow patterns tend to become clearer as multiple records for a particular commodity are analysed together.

**FIG. 1.1** Number of wildlife seizure records in the CITES and UNODC databases 1999–2021

Seizure data interpretation is also complicated because some seizure reports summarize multiple individual incidents under an enforcement operation, while others itemize each incident separately. There are also methodological challenges in converting variously reported seizures to common units of volume, weight or value for analysis.

UNODC strengthens its use of seizure data through triangulation with other indicators, such as evidence of poaching trends for species covered by case studies and insights into market trends from complementary sources.
Data-related challenges and analytical approaches by UNODC to interpretation of seizure data are explored in greater depth and explained in the online methodological annex to this report.

**Case studies and other research**

Like earlier editions of the *World Wildlife Crime Report*, this report draws from additional fieldwork, data gathering and review of the growing academic literature in this field. It also benefits from consultation with a wide range of experts working on related topics, including the members of the Scientific Advisory Committee convened for this report.22

Several case studies and other research outputs were produced by UNODC during development of this report. They were selected in consultation with a broad range of experts and were aimed to be diverse in terms of species, commodity and geographical coverage. Some were designed to gain insights from local, on the ground research of specific illegal wildlife trade challenges. Typically, these focused on early upstream parts of the trade chain for which knowledge about crime structures and motivations was lacking. Other research efforts were selected to update analyses of some of the high-profile illegal wildlife trade issues examined in depth in earlier editions of the report to inform overall insights into recent wildlife crime trends. These drew on in-depth seizure analysis, collation of new information such as market price data, and review of newly published analyses developed in response to CITES decisions.
UNODC also carried out an expert qualitative survey of emerging illegal wildlife trade issues in early 2023 with the intention of identifying important aspects of the issue that might otherwise be missed. Finally, UNODC commissioned a case review and expert interviews on the relationship between wildlife crime and corruption and a research brief on the connections between illegal wildlife trade and climate change. The results of the emerging issues and corruption research have been integrated into relevant chapters of this report.

A subset of the case studies, principally those focused on species-specific analysis, are summarized as annexes in Chapter 6. These and other studies, including some for which research is ongoing, provided important reference sources for the analytical chapters. The main research activities are summarized in Table 1.1. More information on the methods employed is provided in case study annexes and the methodological annex to this report.

Please note that this selection of case studies and other research themes does not signify in any way that UNODC considers these topics to be more important or of greater concern than other wildlife crime themes.
How this report is organized

The structure of this report diverges from the first two editions, in which the thematic case studies comprised the bulk of the reports. After publication of the second edition, UNODC sought feedback from a variety of report users and relevant experts, including members of the Scientific Advisory Committee established to support report development. Based on these consultations, it was decided to produce both an overview of the characteristics of recent wildlife trafficking and a series of systematic analyses of key questions associated with the development of effective responses to this global challenge.

The report chapters are organized as follows:

» Summary, conclusions and policy implications
  Providing an overview of the report findings and implications for public and private sector policymakers and practitioners.

» Chapter 2: Characterizing wildlife trafficking and associated crime
  Taking stock of contemporary developments in illegal wildlife trade based on analysis of seizure data, case studies and other research sources.

» Chapter 3: The impacts and harms of wildlife crime
  Exploring the different types of harm caused by wildlife crime and the available evidence on the extent of them.

» Chapter 4: What is driving wildlife crime patterns and trends?
  Examining evidence of the factors motivating and influencing criminal activity that drives illegal wildlife trade, including the role of corruption.

» Chapter 5: What works to decrease wildlife crime?
  Reviewing evidence of the effectiveness of different interventions taken to reduce criminality and illegal trade.

» Chapter 6: Case studies
  Case study annexes presenting research findings for the topics highlighted in Table 1.1 above.
Endnotes

2 The International Consortium on Combating Wildlife Crime (ICCWC) is the collaborative effort of five intergovernmental organizations working to bring coordinated support to the national wildlife law enforcement agencies and to the subregional and regional networks that act in defence of natural resources. The partner agencies to ICCWC are the Convention on International Trade in Endangered Species of Wild Fauna and Flora (CITES) Secretariat, INTERPOL, the United Nations Office on Drugs and Crime (UNODC), the World Bank and the World Customs Organization (WCO).

8 The initial report of responses to CCPCJ Resolution 31/1 is available at: https://www.unodc.org/documents/commissions/CCPCJ/CCPCJ_Sessions/CCPCJ_32/CRPs/ECN152023_CRP3_.e.pdf.

9 The updated report is available at: https://www.unodc.org/documents/commissions/CCPCJ/CCPCJ_Sessions/CCPCJ_32Reconvened/ECN152023_CRP12_2523139E.pdf and the UNODC response will be made available as document E/CN.15/2024/14.

10 The agenda, inputs and summary report of CITES CoP19 are available here: https://cites.org/eng/meetings/cop.

13 For details of the Kunming-Montreal Global Biodiversity Framework see: https://www.cbd.int/gbf/. Target 5 text is as follows: Ensure that the use, harvesting and trade of wild species is sustainable, safe and legal, preventing overexploitation, minimizing impacts on non-target species and ecosystems, and reducing the risk of pathogen spillover, applying the ecosystem approach, while respecting and protecting customary sustainable use by indigenous peoples and local communities.

17 Wildlife species subject to CITES trade controls are listed in one of three Appendices to the Convention according to how threatened they are by international trade, with differential regulatory measures applicable for trade in species listed in each Appendix.

18 Submission of an annual report on legal trade has been an obligation for Parties states under Article VIII of CITES since the treaty’s inception, while the requirement for submission of annual illegal trade reports was agreed only in 2016.

19 A small number of these reports were not made available to UNODC for analysis on request by the relevant Party. Since closure of the WWCR3 analytical dataset, CITES Annual Illegal Trade Reports for 2022 have been submitted. A regularly updated list of submitted reports is made available on the CITES website here: https://cites.org/eng/resources/reports/Annual_Illegal_trade_report.

21 The CITES Appendices list species subject to international trade controls under the Convention, currently totalling around 40,900 species – including roughly 6,610 species of animals and 34,310 species of plants (https://cites.org/eng/disc/species.php). Trade in many thousands of additional wildlife species is subject to national regulation.

22 The WWCR3 Scientific Advisory Committee was formed to: advise on the scope of and methodology to be used for the report; help identify sources of evidence that can inform research for the report and advise on access to relevant data sources and experts in the NGO and academic communities; and contribute to interpretation and analysis of evidence during development and review of the report to help enhance its quality, scientific credibility and impact. Members are listed in the acknowledgements section of the current report.

Chapter 2
Characterizing wildlife crime
Scope of this report

As for the previous two editions of the World Wildlife Crime Report, this report is focused on crime associated with wildlife trafficking, the harvest of and trade in wildlife species contrary to national law, including, but not exclusively, legislation enacted in fulfilment of CITES obligations.\(^1\)

Precisely which acts constitute crimes in this context depends on the terms of the applicable national legislation, which vary greatly between and sometimes within countries. They may encompass taking from the wild, distributing, transporting, importing, exporting, selling, buying or possessing live specimens, parts or products of wildlife species listed under or otherwise designated by applicable legislation. In some cases legislation may completely prohibit such acts, in others their legality may depend on where or when they take place or whether they have been licensed by relevant authorities.\(^2\)

Wildlife trafficking impacts a very wide range of species of wild animals, plants and fungi, traded locally for domestic use and to international markets. It encompasses a diverse range of commodities, including those used for food, medicine, construction, adornment, display and keeping as live specimens. It includes trafficking in contravention of laws governing large volume and high value natural resource trade sectors, such as those producing timber and fisheries goods. Although sometimes perceived as somehow distinct from other wildlife trade sectors, most food fisheries still come from wild sources, and most timber comes from natural forests rather than plantations, including from illegal sources (Box 2.1).

In practice, most of the analysis in this and previous editions of the World Wildlife Crime Report focuses on the trafficking of species subject to trade regulation under CITES. This is partly because these violations,
illegal timber and fisheries trades

Although most of the global trade in timber from natural forests is not regulated under CITES, a wide range of national legislation applies in countries where harvests take place. This includes national laws governing land use rights, harvest limits, transport, taxation and export controls. In some cases, the details and foundations of such rules can be difficult to describe with precision. While these regulations apply at the national level and not internationally, some importing countries have adopted legal measures requiring proof of legal sourcing that depend on clarification of what this entails. Consequently identifying what proportion of the global timber trade is illegal at some point along the trade chain is challenging.

The global timber trade involves very large flows of goods for domestic use within countries and in international trade. Declared global exports of the main categories of unprocessed timber (roundwood, wood pellets and sawn wood) in 2020 were estimated by the Food and Agriculture Organization of the United Nations (FAO) as totalling over 300 million m³, with an estimated value of $51 billion. Various attempts using different calculation methodologies have been made to estimate how much of this trade is in contravention of relevant national legislation and/or international agreements. Reflecting on strengths and weaknesses of earlier estimates, a study applying an import source method estimated that the value of international trade in roundwood and sawn wood at high risk of illegality was approximately $6.3 billion in 2014.

Global trade in products from wild-capture fisheries has similar characteristics. Most of this commerce involves species and products outside the remit of CITES, but where sourced from waters under national jurisdiction, fisheries trade is often subject to various national legal restrictions on access, catch and trade. In some cases, importing countries require proof of compliance with the national law in source countries, a prominent example being the European Union regulation to prevent, deter and eliminate illegal, unreported and unregulated fishing (in short: the IUU Regulation) entered into force on 1 January 2010. For further information, see “Combatting Crimes in the Fisheries Sector - A Guide to Good Legislative Practices” (International Union of Forest Research Organizations (IUFRO), 2016), https://www.research.unipd.it/bitstream/11577/3268146/1/Ch3%20from%20World%20Series%2035%20-%20Full%20Report%20%28low-resolution%29.pdf.

Global fisheries statistics differentiate production from aquaculture and wild capture, the latter totalling 90 million tons in 2020 according to FAO data. However, from trade statistics it is not straightforward to make this distinction. To give an impression of scale, according to FAO, global fisheries product trade in 2020 totalled 60 million tons, valued at $150 billion. Again, working out the proportion of trade that contravenes relevant national legislation and/or international agreements is not easy. Typically, studies of this subject adopt broad definitions of illicit trade, encompassing products derived from illegal, unreported and unregulated sources. One study estimated that globally between 8–14 million tons of unreported catches were potentially traded illicitly each year during the early 2010s.
whether administrative or criminal, are nearly universally accepted since penalizing CITES violations in national law is incumbent on all 184 CITES parties.1 Also, in terms of significance, CITES-related illegal trade concerns species specifically brought under the treaty’s remit because of concern about existing or potential conservation threat. Focus on this component of wildlife crime also reflects that one of the primary sources of available wildlife seizure data, the CITES Annual Illegal Trade Reports, covers only violations of the treaty’s trade rules. Since CITES trade measures govern cross-border transactions, most of the reported violations concern international trade, generally excluding illegally sourced wildlife that is consumed domestically, such as meat and medicinal ingredients from wildlife sources.

The nature of wildlife trafficking

The illegal wildlife trade differs from other contraband markets, such as the illegal drug trade, in several respects. Unlike many illegal drugs, most wildlife products are legal to possess in many countries around the world. Whether trade in wildlife goods is legal or illegal in one place usually pertains to how they were sourced elsewhere, in another province or country, or whether they were legally transported across national or international jurisdictional borders.

For some species, including many of those listed in CITES Appendix I,4 commercial trade is consistently outlawed across the trade chain from source to end markets. However, facts about legality are not immediately discernible to buyers when wildlife products are encountered on sale. Traffickers take advantage of this complexity by moving illegal wildlife goods towards markets where buyers are either uninterested in the legality of sourcing or find this difficult to verify. They also launder illegal goods into legal trade chains, exploiting weaknesses in shipment traceability requirements or through breeding operations or stockpiles with weak inventory control. As a result, many illegally sourced or traded wildlife products find their way into legal, though illicit, end markets. Although some consumers may knowingly buy illegal wildlife goods, in other cases the legality back to source may not be obvious.

Participants in wildlife crime

Many of the wildlife trafficking participants described in this report would fit the United Nations Convention against Transnational Organized Crime (UNTOC) definition of an “organized crime group”, which essentially encompasses any structured group conspiring to commit crime for financial or other material gain.5 This is very different from the popular notion of organized crime, which centres on mafia-type organizations: groups of professional, violent offenders, working in a strict hierarchical structure who engage in a range of profitable crimes and seek power over territory or business sectors.6 Wildlife trafficking operations by contrast may include diffuse but connected roles, with participants engaged to different degrees in criminality.

Case studies of groups involved in wildlife crime often look more like networks of business-like associations than mafia-type groups. UNODC research in Indonesia (Box 2.2, also the methodological annex) and the case studies on the illegal trade in orchids and seahorses in chapter 7 of the current report provide examples. In several trade chains, the wildlife originates in remote areas where local people find income opportunities from involvement in illegally harvesting wildlife with little or no connection to an organizational structure.7 Trade facilitators exploit business contacts and corrupt relationships as trafficking networks form along the trade chain. Online intermediaries may play important roles in establishing connections between those involved in illegal sourcing and trading as crime networks develop.8 A recent UNODC organized crime threat assessment for Nigeria found this to be the prevalent scenario.9 Participant interviews indicated that wildlife crime appeared to be primarily opportunistic, perpetrated by loosely connected logistics/businesspeople who broker consolidation and transport logistics for both legal and illegal trade of goods and cash in on lucrative products to trade. They finance local people to source wildlife products and then use their existing transport infrastructure to supply international investors. A possible exception to this general rule was the timber trafficking market where well-financed armed groups were believed to be involved. Generally, it seemed that wildlife traffickers in the
country planned their activities like organize criminal groups in terms of risk and rewards, but the group structures were loose, hierarchies unclear, and most were not driven by criminal dynamics.10

Nevertheless, wildlife trafficking does sometimes attract the involvement of highly organized criminal groups. For example, studies in Mexico have examined how and why drug cartels became involved in illegal fishing and trade in totoaba swim bladders or maw, used for medicine and food in Asia and elsewhere.9 This diversification appears to have begun as a territorial power relationship with coastal communities involved in totoaba fishing then developed as a supplementary line of illegal business, employing established smuggling methods and routes with the associated corruption used by the criminal groups for their illegal narcotics trade.12

Similar connections between organized crime groups and trafficking in both illegal drugs and wildlife have been documented in relation to the abalone trade in South Africa.13,14 Additionally, research for the UNODC World Drug Report 2023 included an examination of the nexus between illegal drug trade and crimes that affect the environment in the Amazon Basin.15 It revealed evidence that drug trafficking organizations had been diversifying into new business lines, including trafficking in timber and other wildlife goods.

Another recent example of convergence between wildlife trafficking and other crimes is demonstrated by findings of an INTERPOL-led international police operation, conducted under the joint UNODC-INTERPOL

As part of the research for the current report, a study was initiated by UNODC to gain additional insights from convicted wildlife crime offenders in Indonesia.6 In 2022, the male leader of a wildlife trafficking network was interviewed by UNODC in prison in Indonesia where he was serving time for attempting to barter an unknown quantity of Indonesian wildlife for four lion cubs, one leopard and 58 Indian star tortoises.6 The trade, which was to have taken place in Thailand, was thwarted and the trafficker arrested after the upcoming transaction was detected. The trafficker estimated that he had been involved in between 11–20 illegal wildlife transactions that had involved the bartering of Indonesian wildlife (orangutans, birds of paradise, cockatoos, arowanas, pig-nosed turtles) for big cats. The trafficker said he got involved in wildlife trade through the internet, looking for ways of making money with a small initial investment and without the risks of the illegal drug trade. Following groups on global social media platforms, he learned to connect buyers and sellers. He began with aquarium fish (arowanas) before moving on to big cats. He described working with brokers for both the buyers and sellers (including contacts in Malaysia, India and Pakistan) to set up deals. He used two runners to conduct the physical transactions so that he never touched the wildlife or knew either the initial seller or the final buyer. He made use of airports and seaports where he had connections with informants and corrupt officials. He described his network as his capital.

Other prisoners interviewed in Indonesia at the same time had a background in antiques and collectables, an area where a good network of buyers and sellers was essential in engaging in the illegal trade. Some of the prisoners had made money through their knowledge of antiques markets and their networks for buying and selling these goods. One prisoner reported buying antique (and therefore potentially legal) tiger skin rugs for the purpose of having them made into ceremonial hats that he could resell at a profit, and this practice led him into grey markets.5 Another prisoner reported buying old tusks as part of his antiques business and was arrested when he bought an ivory item with the intent to resell it immediately to a known buyer for a slight mark up.6 Still others were involved in legal aspects of wildlife exploitation, such as the collection of swiftlet nests for international trade, and through these channels made contacts with buyers abroad interested in other wildlife products they could source.8

project DISRUPT aimed to reduce illegal firearms trafficking. The operation covered eight countries in Africa and resulted in seizures of illegal firearms along with illegal wildlife goods, drugs, gold, counterfeit medication and cash. Such convergence of criminal interests in different illicit trade sectors is an area of increasing research and concern.

**Gender dimensions of wildlife crime**

Crime associated with wildlife trafficking involves and affects different human population groups (e.g. genders, ethnicities, age groups or groups of different socio-economic status) in various ways. The UN Sustainable Development (SDG) Goal 5 puts special focus on gender by aiming to achieve gender equality and empowering women and girls, so research for the current report specifically sought insights into gender dimensions of wildlife crime. As gender-informed investigations into wildlife trafficking increase, it is becoming increasingly clear that gender influences the participants, practices, consequences, motivators and results of wildlife crime. However, in the context of wildlife trafficking, datasets are seldom gender or sex disaggregated nor consistently reported on even if collected. Most of the data analysed for this report are not gender disaggregated, i.e. have no information on the gender of the offenders or other participants. Information regarding the roles of actors in the illegal wildlife trade supply chain, whether men, women, indigenous populations or other traditionally underrepresented groups, is also of uneven quality.

With the aim of gaining further insights into gender-related aspects of illegal wildlife crime, UNODC undertook research in 2023 in Colombia, Ecuador and Peru to explore the roles that women and men play in both facilitating and preventing wildlife crime. Overall, the study found a predominant male presence as primary poaching offenders. However, women also play roles along the entire trade chain: women hold an overrepresented role as sellers; are sometimes key actors in the transportation of illegal wildlife products; may actively or passively facilitate wildlife crime committed by men; and may be coerced into supporting male-driven wildlife crime; and play important roles as processors and consumers of wildlife products. In addition, women may also be important advocates against wildlife trafficking.

**Measuring illegal wildlife trade**

As there are many independent markets for illegal wildlife goods, aggregating and comparing them to provide overviews at different geographic scales or other classifications is complicated. First, like all clandestine markets, it is impossible to measure this hidden activity directly. There is a strong reliance on the occasions when illegal wildlife trade is detected, usually when law enforcement seizes a shipment. For some commodities and locations additional information emerges through monitoring online and physical markets, but this is seldom systematic and long-term. Like seizures, such observations give a snapshot of the occurrence of certain wildlife goods at some point along the market chain, rather than a comprehensive indication of the illegal flow.

Counting the number of seizures made and reported is a useful indicator of where law enforcement is happening and at a crude level what is being discovered. However, seizure numbers alone do not offer great insights into the significance of what has been seized. A critical consideration is what is the purpose of an assessment based on aggregation of seizures for different wildlife goods? What makes one wildlife seizure more important than another? How is it best to add or compare seizures of e.g. logs and butterflies in a way that appreciates the relative importance of each? How can the significance of seizures in different geographic regions or for different years be compared?

Some commodities, such as corals, are frequently taken from tourists at airports in small amounts unlikely to be a threat to wild populations, while others, like totoaba fish swim bladders, are rarely encountered although illegal trade has serious implications owing to the species' rarity and the threat of by-catch of Critically Endangered vaquita porpoises when totoabas are caught.
UNODC research in Colombia, Ecuador and Peru aimed to explore the roles that women and men play in both facilitating and preventing wildlife trade-related crime. Research carried out in 2023 included a survey of wildlife markets in 21 locations (mainly cities\textsuperscript{a}), interactions with 103 sellers from different backgrounds, and 62 semi-structured interviews with stakeholders (e.g. government officials, community representatives, non-governmental organizations), gender disaggregated seizure data analysis and a literature review.

Some key findings of this research are summarized here. Other findings have been included in the relevant sections of this report as gender aspects cut across the various themes discussed within it. The full research findings will be published separately in the form of a research brief.

- **Women** are the primary sellers of wildlife products (both legal and illegal), evidenced by both the surveys and interviews.

- **Medicinal markets**, driven by traditional Amazonian medicinal practices, exhibit distinct gender associations. **Women** are almost exclusively the keepers of traditional medicinal knowledge as well as being the actual practitioners and sellers. **Men** are reported as being the main extractors (often poaching) and processors of the wildlife products for medicinal use. However, the processing and preparation of other wildlife products was mainly reported as a role for women.

- **Artisan markets**, driven in part by tourism, play a significant role in driving demand for species in the Amazon region (teeth, bones, skins, from species such as bear, otter, dolphin, jaguar). Most of the artisans and sellers of these products are women, often from indigenous communities.

- The most visible demand for wildlife in markets in the Amazon region is for **wild meat** driven by domestic markets. Again, women comprise the majority of sellers of these products, and this trade chain involves interesting social drivers (e.g. gendered cultural practices, gendered economic factors) that warrant further research.

- **Poaching** is reportedly almost all done by **men** although women occasionally join in groups with families (e.g. children, grandparents, partners). Women may exhibit a higher degree of participation in poaching related to specific species. For example, women were more connected to poaching activities related to fishing (small fish for consumption and ornamental fish), marine turtle eggs, and live birds. Poaching/illegal collection from the wild was found to be carried out for multiple purposes such as the meat/food trade, medicinal use, the pet trade or for souvenirs and ornaments. Some of this trade occurs for local consumption, some have a wider international aspect, such as souvenirs. The species observed for sale at markets during the research and those reported in seizures included reptiles (e.g. turtles, snakes and crocodilians), birds (e.g. finches and parrots), mammals (e.g. agoutis, armadillos, jaguars and dolphins).

  - Women often act as intermediaries in the live animal wildlife trade. They often become caretakers responsible for looking after live animals prior to sale or before the animals are moved on to other intermediaries.

  - Knowledge of the existence of someone described as a **high-ranking woman wildlife crime leader** in the region was disclosed in five separate interviews during the study.

- **Indigenous women** play important roles as **defenders** of land, environment, and wildlife throughout the region. Findings from the study show that a **mixed group of men and women land defenders was more successful and less confrontational** when confronting poachers\textsuperscript{b}.

  - **Women** have been reported to face different repercussions for defending territory, such as threats and acts of sexual violence and threats and acts of violence against their children.

- As **consumers**, the practice of keeping wildlife as pets is prevalent, with demand coming from both men and women in the Amazon region. However, it was widely perceived that women exhibited a greater interest in keeping wildlife as pets for companionship, with birds being particularly noted in this context. This may be because many women are obligated to stay at home to fulfil household and childcare duties. Pet keeping practices may have increased during the COVID-19 pandemic.

\textsuperscript{a} Markets surveyed included in Colombia: Bogota, Florencia, Leticia, in Ecuador: Coca, Limoncocha/Pompeya, Macara, Puyo, Quito, in Peru: Iquitos and Pucallpa.

\textsuperscript{b} To understand further the impact of wildlife crime on indigenous women, see UNODC, “Toolkit on Mainstreaming Gender and Human Rights” (Vienna, Austria, 2023).
Furthermore, it is difficult to identify meaningful common units of measurement to aggregate and compare wildlife seizures. Measures of quantity reported in seizure records are sometimes expressed in terms of numbers of live animal and plant specimens along with counts of parts and derivatives, but sometimes quantities are expressed by units of weight, volume, or other dimensions. Using a single consistent unit of measure may be viable when trying to understand the importance of illegal trade flows for a single wildlife commodity, such as expressing how much elephant ivory might be in trade by weight as the average weight of tusks per elephant can be estimated, and this provides a basis for comparison with other data sources, such as population numbers and poaching incidents. However, when looking across a range of commodities, weight alone may not be an informative expression of significance. Logs are heavy and butterflies are light, but a single butterfly may bring more criminal profits than a stack of logs. Similarly, trade in a small number of rare orchids may pose a far greater risk of extinction to a species than the movement of hundreds of thousands of juvenile eels does to another. This is because different animals and plants have different population sizes, reproductive potentials and responses to harvest.

For some analyses in the current report, as in earlier editions of the World Wildlife Crime Report, a value-based index is used to facilitate aggregation of seizure records for different species and commodities. Properly caveated, assigning an economic significance to wildlife seizures gives a way of aggregating and comparing data that can serve several purposes. Particularly in the study of organized commercial-scale wildlife crime, it is the value of the wildlife that motivates key participants along the trade chain who break the law. Price is also often indicative of scarcity, so it bears some relation to the ecological significance of the seizures.

The standardized seizure index used by UNODC for some aggregated analyses of wildlife seizures employs declared import/export value data from the Government of the United States of America and price reference points from several other sources to create an expression of relative value for different species-product combinations. It is also important to stress that the standardized seizure index is simply an aggregation methodology and is not intended for calculating total market value, a topic discussed later in this chapter. Therefore, absolute values for the standardized seizure index are not provided in this report, only trends and relative share.

**Insights from seizure data**

### What species are targeted?

According to the WWCR3 analytical dataset, seizures during 2015–2021 involved illegal trade in around 4,000 wildlife species, approximately 3,250 of them listed in the CITES Appendices. The largest numbers of individual seizures reported during that period involved corals, crocodilians and elephants (Figure 2.1).

The same seizure data summed using the standardized seizure index shows the dominance of timber (cedar and rosewood) species (Figure 2.2).

Just 15 broad markets comprise the bulk of the observed illegal wildlife trade based on standardized seizure index analysis, split by animals and plants (Figure 2.3). However, the extent to which this analysis is representative of illegal trade overall is uncertain, owing to seizure-related biases and gaps in price index reference data.

### What commodities are illegally traded?

Species groups are traded illegally in a range of forms, which provide insights into the motivations for their trade. These include uses as food, medicine, clothing, fuel, adornment, building material, decoration, entertainment, study and companionship.
During the period 2015–2021, based on the number of seizure records, coral pieces were the most frequently reported item in illegal wildlife trade followed by live specimens, which are generally part of the pet or ornamental plant trades although may also be used in medical research (e.g. monkeys) or processing into other products, like meat. They were followed by medicines, meat, shells and small leather products (Figure 2.4). Roots and extracts were also prominent in the dataset, which are likely used for medicinal purposes.

Among the commodities represented in seizure records between 2015–2021, live specimens involved both animals (e.g. parrots and turtles/tortoises) and plants (e.g. cacti and orchids) (Figure 2.5). Medicine shipments involved mainly plants (costus root, aloes and orchids), while meat seized mainly involved crocodilians, queen conch and tri-

dacna clams. Items reported as “bodies” (whole dead specimens) represented a diverse group with seahorses, carnivores, corals, crocodilians and birds of prey all reported in seizures. Extracts mainly involved plants (cacti and aloes).

This seizure distribution illustrates the different forms in which the same species groups are illegally traded. For example, pangolins are illegally traded as scales, meat, bodies and also as live specimens; lizards are traded as meat, small leather products and live specimens; and orchids are traded as roots, medicines and live specimens.

Recent global trends in illegal wildlife trade

Assessment of illegal trade trends through analysis of seizure data requires caution because changing levels of enforcement effort and reporting introduce biases to the results. Nevertheless, with appropriate caveats, useful insights can be gained.

The annual number of seizure records in the WWCR3 analytical dataset varied considerably during the period 2015–2021 (see Figure 1.1 in Chapter 1). The requirement to submit annual illegal trade reports under CITES began with data for 2016, therefore the number of records in the dataset for 2015 was lower at around 13,000. From 2016–2019 there were approximately 25,000 records per year followed by a drop to around 15,000 records per year in 2020 and 2021. This could reflect impacts of the COVID-19 pandemic, such as through decreasing poaching and trafficking activity, reduced enforcement control or obstacles to reporting or disruptions in transportation or any combination of these factors. Research by UNODC to assess the impact of the COVID-19 pandemic on different forms of crime has documented a clear reduction of law enforcement and criminal justice capacity during and shortly after the pandemic.28 29

In terms of illegal trade volumes, trends can be examined for seizures reported by numbers of individual specimens and those reported by weight during the period 2015–2021 (Figure 2.6). For those reported by weight there was a significant peak in 2017–2018, a drop in 2019 and smaller increases again in 2020 and 2021. For transactions reported by total number of specimens (where no weight was reported) there was a peak in 2019. It is important to note that the volume of illegal trade in the same wildlife species can be reported by number of specimens or by weight or both and sometimes the reporting can shift between these inconsistently, without an actual change in the trade pattern. Therefore, some of the variation might be related to changes in reporting rather than actual changes in seizure patterns.30

UNODC is populating the indicator on progress to end trafficking of protected species of flora and fauna under the framework of the Sustainable Development Goals (SDGs). A SDG indicator 15.7.1 is based on a comparison of CITES legal trade records and seizure records from CITES annual illegal trade reports using the same aggregation method employed for the standardized seizure index explained above. The intent is to provide a proxy for the share of the total market that is known to be illegal, with the caveat that seizures measure an unknown percentage of illegal trade and the total volume of wildlife trade may vary over time due to a variety of factors, including economic cycles. A decrease in the index value would proxy a reduced proportion of global wildlife trade being illegal.

An initial estimate of the indicator suggests that globally the intercepted illegal wildlife trade as a proportion of all wildlife trade (legal and illegal) increased from 2017 onwards, reaching its highest levels during the COVID-19 pandemic in 2020-2021 (Figure 2.8a). Wildlife seizures made up around 1.4 to 1.9 percent of global wildlife trade in 2020-2021. Looking separately at the indicator trends for animal and plant trade shows that plant transactions were responsible for the elevated combined indicator for 2020 and 2021.

Considering the seizure and legal trade index trends separately, the overall SDG indicator trend appears to be most influenced by an increase in the measure of seizures from 2020 onwards (Figure 2.8b). Examination of underlying records in the two datasets shows that the increase at the global level in wildlife seizures in 2020-2021 responds mostly to new regulation (CITES-listing) of high-value timber species from South America and related enforcement actions resulting in seizures. Global trends in the measure of legal wildlife trade are heavily affected by trade flows in Asia, which made up 50-70 percent of global legal trade annually during 2016-2021. Most regions saw a decline in legal trade in 2020 followed by a slight recovery in 2021.

**FIG. 2.8b** Trend in the estimated value of wildlife legal trade and seizures 2016–2021

Sources: CITES Trade Database, CITES Illegal Trade Database and World WISE

---

b. The indicator is calculated for CITES-listed wildlife only, as CITES provides a common regulatory framework internationally together with systems for data collection on legal trade and seizures of CITES-listed wildlife. Seizure data only account for the portion of illegal wildlife trade that is detected. In addition, the listing of species on CITES changes over time. Therefore, caution should be practiced when interpreting the results.
Using the standardized seizure index to aggregate all seizures however reported, there is a generally upward trend during the period 2015–2021 (Figure 2.7). However, when illustrated separately for seizures involving animals and plants there is a significant difference. For seizures of animal species there is a gradual increase from 2015–2019 then a significant decline to a lower level for 2020 and 2021. By contrast, for seizures of plant species there is a small peak in 2017 and sharp increases in both 2020 and 2021. The former reflects some unusually large seizures of rosewood shipments in 2017 while the latter is heavily influenced by some very large seizures of cedar (Cedrela sp.) timber in one range state, possibly linked to implementation and enforcement action in relation to the recent listing of this tree genus in CITES Appendix II, which entered into force in August 2020.

Examining the top species groups reported by number of seizures per year during the period 2015–2021 shows that the share of coral species in seizures decreased significantly while the share of bird species increased over the same period (Figure 2.9). The former may reflect reductions in air passenger movements related to the COVID-19 pandemic as corals are often seized from passenger baggage.

Examining trends in species composition aggregated using the standardized seizure index rather than a simple count of seizure numbers, the pattern is rather different (Figure 2.10). For plant species, the dominant trends are the aforementioned 2017 peak in rosewood seizures and the upsurge in cedar seizures in 2020–2021. For animal species, seizures of rhinoceros, pangolin and elephant products dominate across the full period, with the decrease in the index in 2020 and 2021 being fairly consistent across all the illustrated species groups.

The share of commodity types based on the number of seizure records also changed over 2015–2021. The declining trend in corals from 2020 can be observed again, while the share of seizures of live specimens increased during the same period, which could perhaps reflect increased restrictions on the movement of live animals in the wake of the COVID-19 pandemic and concerns about the spread of zoonotic diseases (Figure 2.11).

* Both plants and animals
As explained earlier in this chapter, in addition to the general caution that needs to be applied when inferring illegal trade flows based on the partial view afforded by seizure records, aggregation across a wide range of species, commodities and reporting units presents important interpretation challenges. To examine trends in more detail, particularly the likely influence of the COVID-19 pandemic on wildlife crime, trends for four of the individual wildlife products addressed by case studies in this report were plotted as their percentage change in total weight reported from a 2015 baseline (Figure 2.12). Trends for the same four products were also plotted by absolute total weight, reported with an adapted scale to aid comparison (Figure 2.13).

As discussed in the individual case studies, seizure data could infer peaks in illegal trade and/or enforcement action for all these commodities between 2017–2019. For rosewood, seizure records appear to show a dip in illegal trade flows during 2018–2020, while for elephant ivory, rhinoceros horn and pangolin scales, a 2019 peak was followed by a significant drop in 2020. For all four commodities there was some increase in volumes reported for 2021, but well below the 2019 peak level. However, it is challenging to interpret the sudden changes as the result of reduced trafficking or a reduced capacity of countries to intercept trafficked commodities during the COVID-19 pandemic restrictions. An analysis that goes beyond seizures can help to understand better what happened before and during the pandemic.

**Did the COVID-19 pandemic have an impact on wildlife trafficking?**

Over the past decade, a range of interventions has been pursued to address illegal wildlife trade, including market closures, better coordination and pursuit of enforcement action, and consumer behaviour change campaigns. Hence changes observed before, during and after the COVID-19 pandemic could be the result of a combination of these factors and not simply down to disruption caused by it.

The UNODC research in the Amazon region of South America to explore the roles that women and men play in both facilitating and preventing wildlife trade-related crime also provided some...
insights into local circumstances affected by the pandemic. According to many of the sellers surveyed, the pandemic catalysed a trend towards more rigorous enforcement and closures of wildlife markets. Many sellers reported not being able to trade wild animals and their derivatives openly during and immediately after the pandemic owing to stronger enforcement and fear of wildlife/animals as a source of disease transmission. Some of those interviewed said:

“I have been working here for 50 years. Before animals were sold in the square, but since the pandemic it’s been prohibited.”

“Animals are no longer traded here because the mayor prohibited their sale after the pandemic since it was said that they could be sources of coronavirus transmission.”

Despite not being able to sell or buy wildlife openly in markets, many sellers and interviewees in this study said that the demand for wildlife overall did not decrease. Instead, wildlife use increased as the availability of imported goods decreased during the pandemic, forcing local people to rely more heavily on wildlife products to sustain their livelihoods. According to one interviewee:

“The markets have changed since the pandemic; you’re prohibited to sell a lot of products from the jungle now. If you want something you have to ask and then come pick it up later.”

While another interviewee said that some illegal items continued to be available, albeit concealed:

“You can get wild meat, it’s not as much as before and you might not see it but, is always in the market.”

The United Nations Conference on Trade and Development (UNCTAD) statistics show a sharp downturn in global trade in 2020 as a consequence of border restrictions and other logistical disruptions resulting from the pandemic and a decline in global demand as health and economic crises unfolded. However, recovery began before the end of that year and the overall decrease in global trade in goods from 2019–2020 was less than 10 per cent. Global trade in goods in 2021 increased rapidly and reached a higher annual total than that reported in 2019 before the pandemic. However, within the global trend there were major differences in how the pandemic affected different types of merchandise.

Looking in more detail at global transport trends, maritime container freight volume appears to have been little affected by the pandemic and annual air freight volume reduced in 2020 by around 15 per cent but bounced back to previous levels in 2021. The most marked change during 2020 was the reduction in air passenger numbers, down over 60 per cent compared to the previous year and recovering slowly in 2021 (Figure 2.14). This decrease may be reflected in the lower number of wildlife seizures in 2020 and 2021, although perhaps it is less significant in terms of trade volumes given bulk shipments are not moved in passenger baggage. It is also worth noting that both maritime and air freight costs soared during the pandemic.

Some reported wildlife seizures take place in markets or storage locations rather than during shipment. Even for those seized on the move, the mode of transport is not always reported so it is difficult to establish robust trends. However, from the limited information available on transport mode in the WWCR3 analytical dataset, the reported percentage of seizures linked to air transport decreased greatly in 2020–2021, likely reflecting the pandemic disruption to passenger travel (Figure 2.15). It is also noteworthy that the percentage of seizures from
As discussed in chapter 4 of the current report, demand driving illegal wildlife trade is segmented into several different use sectors with distinct characteristics. It is therefore unreliable to generalize about the possible impacts of the pandemic on levels of consumer demand for illegal wildlife goods. Instead, taking stock of global economic trends, it is noteworthy that a comprehensive index of consumer confidence showed a significant downturn in 2020, recovering to pre-pandemic levels by mid-2021.42

To ascertain whether the reduction in some types of wildlife seizures during 2020–2021 might be a sign that enforcement effort had decreased owing to workplace restrictions or other factors, trends in reported seizures from other contraband markets were examined.

A review of available data indicated different trends have been observed in the global interception of various forms of trafficking. Records of cocaine, for example, reached global highs during 2020 and 2021 (Figure 2.16) and methamphetamine seizures in East and South-East Asia also remained high during the same period (Figure 2.17). However, the detection of victims of trafficking in persons, for the first time in 20 years, fell by 11 per cent between 2019–2020.43 It is unclear to what extent these contrasting trends during the pandemic period reflect differences between markets or variation in enforcement priorities.
What is the overall scale of illegal wildlife trade?

Although seizure data represent an unknown proportion of actual illegal trade flows, they do provide an indication of the minimum scale of wildlife crime. However, as explained above, calculating even this minimum volume is not straightforward. Wildlife commodities are recorded in seizures using different units of measurement appropriate to their individual characteristics. The majority of seizures are reported either by numbers of individual specimens (typically live animals and plants or manufactured items) and those reported by weight (typically bulk goods, such as timber or ivory).

Based on the WWCR3 analytical dataset, the total number of individual wildlife specimens reported by number during 2015–2021 was just under 13 million, or on average 1.84 million specimens per year (where no weight was reported). Summing the quantity of seizures for this period reported by weight (without any conversions) reveals a total of close to 17,000 tons, or on average 2,400 tons per year.

Another way to represent the scale of illegal wildlife trade during this period is to estimate its monetary value. Doing this in a meaningful way even for known seizures is remarkably difficult because the “value added” by a trafficker is in moving the product past enforcement barriers from its source to its destination market. Therefore, the value of contraband is highly dependent on where in the market chain it is encountered.
One of the biggest problems with the prevailing estimates of the value of the illegal wildlife trade is definitional. It is often unclear what is being evaluated, or different types of valuation are mixed. Some estimates provide the monetization of the environmental cost related to wildlife trafficking together with lost governmental revenues from user fees or taxation.\(^a\) This type of estimates helps to recognize the harm and impact of wildlife crime on social, economic and environmental development, but it provides little information on the actual profits made by traffickers and the size of the actual financial resources that are exchanged when wildlife is trafficked.

From a crime perspective, it is useful to estimate a monetary value of the illegal wildlife trade to understand the size of the illegal profits generated and the related illicit financial flows. These aggregates help to assess the financial motivations associated with the illegal trade and the broad magnitude of illicit financial flows that are traded within and across borders. This can support law enforcement and financial institutions to appreciate the magnitude of the threat.

UNODC has undertaken studies for selected species to estimate the total value of gross illegal income generated by illegal wildlife trade across the entire supply chain, considering the markup price at each stage of the chain.\(^b\) Estimation of the potential profits made by traffickers involved subtraction of processing and handling costs and the calculation of a net-value income associated with trafficking.

Within the total valuation of an illegal wildlife market, it can be useful to look at the illicit income made at each stage of the supply chain as different actors may be involved and each stage may require a different response. Values of wildlife commodities at the retail stage can greatly vary depending on factors such as the amount being bought (e.g., larger quantities sold at a lower price), differences in the quality of the actual batch (e.g., the same timber species could produce very different quality timber depending on the circumstances in the habitat of harvest) or the characteristics of the given market (e.g., the same products can be sold for different prices at various markets). Some markets that have been monitored, like the price of ivory in Asia, have shown price variations of 250 per cent over three years.\(^b\)

The nature of illegal wildlife trade is that goods traded illegally as raw materials may subsequently enter legal processing industries and retail markets. In such cases, although clearly still associated with illegality upstream in the supply chain, profits linked to value added in the legal market may have limited significance for gaining insights into criminal motivations. In such cases, the size of the wholesale market may provide greater insights into the profit motivations for criminals organizing the illegal supply.

**BOX 2.5 Estimating the value of illegal wildlife trade**

**BOX 2.6 Estimating illegal trade value for elephant ivory and rhinoceros horn**

The *World Wildlife Crime Report 2020* looked at two of the best-known illegal wildlife markets—elephant ivory and rhinoceros horn—and estimated the illicit gross income associated with trafficking in these commodities. They were based on estimates of the annual supply to the market using CITES evaluations of poaching levels and price observations along the trade chain. The report also estimated associated illicit financial flows, the cross-border flows of resources that are illicitly generated, transferred or used, taking into account both income and costs at different steps along the trade chains for these commodities.

The report estimated annual illicit gross income from elephant ivory trade of $400 million (range $310–570 million) during 2016–2018. For rhinoceros horn the annual illicit gross income during the same period was estimated as $230 million (range $170–280 million).

Considering a range of possible scenarios and numerical simulations, average estimates of associated annual illicit financial flows were $240 million for elephant ivory and $163 million for rhinoceros horn.

For the different stages of the supply chain, it was calculated that for ivory, within the total of $310–570 million annual illicit income, $260–490 million was generated at retail level, $38–60 million from international trafficking, $7–11 million by runners and brokers, and $8–13 million by poachers. For rhinoceros horn it was calculated that within the total of $170–280 million annual illicit income, $120–160 million was generated at retail level, $28–79 million from international trafficking, $7–15 million by runners and brokers, and $6–43 million by poachers.
or gross criminal profits, lost governmental revenues, lost value to the economy, loss of ecosystem services, or some other metric. Some estimates may combine these unlike measures.

While it may be very difficult to give an accurate estimate of the size of the market overall, estimates of the value of illegal trade flows can be made for some of the best-known markets, such as those for elephant ivory and rhinoceros horn (Box 2.6). This is because knowledge of population losses to poaching can be used in combination with seizure data to estimate likely trafficking flows. Availability of price information from defined points on the trade chain allows estimation of market size. Such estimates can be summed in a “bottom-up” approach to gain a basic insight into the scale of illegal wildlife trade flows.

The elephant ivory and rhinoceros horn markets are among the most prominent in the illegal trade in CITES-listed species. Using the calculations summarized above, proceeds from international trafficking of unworked rhinoceros horn and ivory may have totalled between $66–139 million a year during 2016–2018. This is a substantial sum, although bear in mind that this represents gross income to traffickers rather than net profit. It is also apparent that significant additional value associated with this trafficking is generated through subsequent illicit retail sales. As shown in Figure 2.2, together these two commodities constitute just under 20 per cent of reported wildlife seizures based on the standardized seizure index comparison.

For context, an analysis of legal trade in CITES-listed species during 2016–2020 estimated an average annual value of approximately $1.8 billion for trade in all CITES-listed animal species and approximately five times this figure, $9.3 billion, for CITES-listed plant species. As this calculation was based on declared import values and wholesale market prices, it is roughly comparable to the estimates for the international trafficking stage in the ivory and rhinoceros horn trade value analysis.

Finally, when comparing these figures with other estimates of global illegal wildlife trade, it is critical to recall that there are very large sectors of the market,
such as illegal flows of timber and fisheries products derived from species not regulated by CITES, for which seizure records are not currently available in the analytical dataset.

**Geographic variation**

Wildlife seizures in the WWCR3 analytical dataset were recorded as having been made in 162 countries and territories during 2015–2021, with an additional 82 countries and territories implicated in the trade chain for these transactions. Together they demonstrate the global nature of illegal wildlife trade (Map 2.1).

For some records, information on the country of shipment and next destination are provided, but in many cases this is unknown or unreported. Even when reported, it is often unclear whether the country of shipment is the actual country of origin where wildlife was harvested or whether the shipment destination is believed to be the intended end market for the goods seized.

In international wildlife trade, commodities are moved from source countries to consumer countries sometimes via multiple transit points and seizures can be made at any point in the trade chain. Therefore,
any pattern shown by region in this section must be treated with some caution as it is not necessarily clear from the data at which point of the trade chain the seizure was made and so what the role of that region in the chain may be. Also, some regions are more consistent in reporting seizures than others, therefore Figure 2.18 and Map 2.1 likely do not provide a strong indication of where wildlife crime occurs. Based on the number of seizure records in the WWCR3 analytical dataset, the African region was the location of the smallest number of records for 2015–2021. The uneven geographic distribution must be taken into account when interpreting the data at the regional or global levels. About half of the recorded seizures were made in Europe and Oceania for the period 2015–2021. However, when seizures are analysed on the basis of the standardized seizure index, Asia and Africa emerge as the most significant regions where seizures took place (Figure 2.18).

Again, aggregated by standardized seizure index, seizures in Asia were distributed across subregions as follows (percentage of global total): South Asia 9 per cent; South-East Asia 4 per cent; East Asia 3 per cent. Virtually all the seizures reported for Africa (19 per cent) were made in the sub-Saharan subregion. In terms of global trade
flows, a majority of seizures between 2015–2021 was made up of shipments from sub-Saharan Africa and South Asia, based on seizures where the shipping origin was specified (44 per cent of all the records) (Figure 2.19).

In 2015–2021, elephant, carnivore and pangolin items were all in the top five species groups seized in Africa and Asia (Figure 2.20). However, while these was a large share of rosewood timber seizures in Asia, there was a smaller proportion in Africa where it did not make one of the top five species groups seized. Coral, crocodilian and snake items were more prominent in the other three regions, with parrots and cockatoos prominent in the Americas and bivalve molluscs in Oceania. Plants also comprised a significant proportion of the records in Europe (e.g. aloes and cacti) and in Oceania (e.g. costus root and ginseng).

Differences in the charts by number of seizure records (Figure 2.20) and aggregated by standardized seizure index (Figure 2.21) can be observed for the same regions. For example, in Asia the share of rosewood seizures aggregated by standardized seizure index was over 35 per cent for 2015–2021 but by number of seizure records, only 17 per cent. In Europe, eels did not feature in the top species groups based on number of seizure records, but they represented 29 per cent by aggregated standardized seizure index. These examples illustrate the importance of interpreting the data from multiple perspectives and understanding which aspect of the data is useful to look at depending on what the interest is.
FIG. 2.20  Percentage share of seizure records by species group for each region 2015–2021

* Other Liliales includes agave, snowdrop and yucca species
** Other Sapindales includes guaiacum, holy wood and mahogany species

FIG. 2.21  Percentage share of seizures by species group for each region aggregated by standardized seizure index 2015–2021

Sources: CITES Illegal Trade Database and World WISE (WWCR3 analytical dataset)
* Other Myrtales includes eucalyptus and ramin species
** Other Sapindales includes guaiacum, holy wood and mahogany species
Across the regions significant differences can be observed in the share of wildlife species groups seized between 2015–2021 based on the standardized seizure index analysis. In Asia, a large share of seizures involved timber followed by pangolin items. In Africa, pangolin, rhinoceros and elephant items together made up over 95 per cent of all seizures. In Europe, eels led followed by agarwood. In the Americas, timber (cedar) was by far the top taxonomic group using this metric (79 per cent), followed by crocodilian and rosewoods (5 per cent and 3 per cent respectively). In Oceania, the top taxonomic groups involved crocodilians, costus root, snakes, ginsengs and cacti in order of importance.

The main wildlife commodities seized between 2015–2021 based on the number of seizure records and standardized seizure index were also analysed (Figures 2.22 and 2.23 respectively). Live specimens constitute an important group in both analyses by making it into the top five in four regions by both metrics. By number of seizure records (Figure 2.21), three regions had medicines in their top five: Americas, Europe and Oceania. Aggregated by standardized seizure index (Figure 2.22), horn seizures were in the top five for three regions: Africa, Asia and Europe. Similarly, seizures of small leather products also featured prominently in three regions: Americas, Europe and Oceania.

Endnotes

1 The term “wildlife crime” is sometimes used to cover a wider scope of concerns than those addressed by the current report, such as illegal persecution, killing, poisoning, or poaching of wildlife for reasons not related to trade, as well as the unauthorized alteration or destruction of habitats in contravention of environmental law. For example: https://stopwildlifecrime.ee/.

3 Article 8 (1) of the Convention requires, “The Parties shall take appropriate measures to enforce the provisions of the present Convention and to prohibit trade in specimens in violation thereof. These shall include measures: (a) to penalize trade in, or possession of, such specimens”.

4 CITES Appendix I lists species that are the most endangered among CITES-listed animals and plants. CITES prohibits international trade in specimens of these species except when the purpose of the import is not commercial, for instance for scientific research. Article VII of the Convention provides for a number of exemptions to this general prohibition.

5 Article 2(a) of the Convention defines “organized crime group” as “A structured group of three or more persons, existing for a period of time and acting in concert with the aim of committing one or more serious crimes or offences established in accordance with this Convention, in order to obtain, directly or indirectly, a financial or other material benefit.” Serious crime is further defined as crimes punishable by four or more years in prison, which would include many forms of wildlife crime in some of the largest markets in the world. The crimes articulated in the Convention include conspiracy, money laundering, and corruption, all crimes commonly associated with wildlife crime. See: https://www.unodc.org/documents/treaties/UNTOC/Publications/TOC%20Convention/TOC_ebook.pdf.

7 For example, in 2022, UNODC interviewed 11 people incarcerated in Indonesia for poaching activities, of whom five reported not being aware that their activities were illegal. See the online methodological annex for details of this research. Similarly, many species protected under CITES Appendix II feed into large legal markets, like the seahorse case study detailed in this report, where many retailers may not know of the illegal origins of their products.

10 Ibid.

12 Ibid.

26 Import/export declared value data published by the Government of the United States are supplemented by UNODC wholesale price estimates for some commodities and market price information for plant species compiled by UNEP-WCMC.

27 Price index reference points were applicable to approximately 52 per cent of seizure records in the dataset (approximately 56 per cent for animals and 40 per cent for plants). This is in part because index values are excluded for many manufactured goods, such as packaged medicines, because reported quantities are unreliable. For example a report of one item could be a single medicinal pill or a package containing hundreds of individual pills.

30 Notes: reported number of specimens includes all description codes whether live, parts, derivatives or products. The annual illegal trade report template allows for reporting both weight and other quantities (e.g. number of specimens or volume). In this figure, weight was presented in the chart whenever weight was reported, while the number of specimens totals include only records where weight was not reported to avoid double-counting.

31 CITES Appendix II lists species that are not necessarily now threatened with extinction but that may become so unless trade is closely controlled. It also includes so-called "look-alike species", i.e. species whose specimens in trade look like those of species, listed for conservation reasons. International trade in specimens of Appendix II species may be authorized by the granting of an export permit or re-export certificate if the relevant authorities are satisfied that certain conditions are met.

33 A report of the findings of the UNODC research on gender dimensions of wildlife crime in Colombia, Ecuador and Peru will be published separately in future.

Chapter 3

Impacts and harms
The preceding chapter of this report provides insights based on seizure data into contemporary patterns and trends in wildlife trafficking and considers evidence of the nature of related criminal activities. This current chapter takes stock of the types of harms that can result from wildlife crime. Such analysis was not a feature of the first two editions of the World Wildlife Crime Report but is included here as better understanding of these harms can shape perceptions of wildlife crime’s significance and inform both policy responses and prioritization of actions.

Harms resulting from wildlife crime include a range of interlinked negative environmental, social and economic, and governance impacts (Figure 3.1).\(^1\,^2\,^3\,^4\) Concern about these different types of harm is reflected across national and international policies and law, although the full breadth of impacts is rarely addressed.

Assessing the scale of each of these factors is not always straightforward. In some cases, wildlife crime causes harm that is direct and demonstrable, such as environmental defender casualties during conflict with poachers or the relationship between ivory trade, poaching and declining elephant populations. Establishing other causal links between crime and harm often involves considerable complexity, such as estimation of lost government revenue or the impact of illegal wildlife harvests on ecosystem functions and human well-being. There are also potential harms (rather than those already realized) for which evaluation requires a risk-based approach, such as assessment of the threat of zoonotic disease emergence.

Often the level of concern is not simply a function of the level of wildlife crime taking place but is also prompted by where and how it takes place. For example, smuggling of potentially invasive species to an island nation home to vulnerable endemic species is likely a greater concern than the same illegal trade between neighbouring continental countries.\(^5\)

Importantly, harms may also result from responses to wildlife trafficking, including policy interventions, regulatory choices and criminal justice action. Some trade-offs between the positive and negative impacts of regulation are likely inevitable.
Environmental harms

Species overexploitation

The most prominent environmental harm caused by wildlife crime and related illegal wildlife trade is degradation of the world’s biological diversity through overexploitation, resulting in population reduction and extinction threats to wild species. Species diversity is a critical aspect of the functioning ecosystems that support all life on earth. The threat of species overexploitation was identified as the second most significant driver of global biodiversity loss after land-use change by the Intergovernmental Science-Policy Platform on Biodiversity and Ecosystem Services (IPBES). Concern about overexploitation motivates much of the national legislation affecting wildlife trade worldwide and it is the rationale for the international trade regulation measures now subscribed to by 184 states that are contracting Parties to CITES.

The threat to species as a result of wildlife crime is typically highlighted using prominent and well-documented examples, such as poaching of elephants, rhinoceros, and tigers to supply illegal markets. Such species attract significant research attention and
resources. Consequently, there is comparatively extensive information about population numbers, breeding biology, poaching levels, and trade flows. This knowledge provides a solid basis for assessing the impact of illegal trade. However, this is not the case for most species affected by wildlife crime. Some of the clearest examples of conservation harm caused by wildlife crime receive comparatively little attention. For example, illegal collection for trade is believed to have caused the recent extinction of several succulent plant species with extremely limited areas of distribution in South Africa. Illegal trade has also led to severe depletion of rare orchids, including newly described species stripped from their habitat soon after discovery. Other examples include species of reptiles, fish, birds, and mammals for which illegal trade appears to have played a major role in local or global extinctions.

To gain some insight into the relationship between wildlife crime and extinction risk, an analysis was carried out of the assessed conservation status and threats to wildlife species recorded in recent seizure data available to UNODC. For each species recorded as seized during the period 2015–2021 in the WWCR3 analytical dataset, information on its global conservation status and current population trend was extracted from the IUCN Red List of Threatened Species, the most comprehensive global information source available on extinction risk to species.

This analysis was carried out for all mammal, bird, reptile, and amphibian species recorded as seized as these are the most comprehensively assessed species groups in the IUCN Red List (Figure 3.2). Combined these four species groups represent just over 40 per cent of all recorded seized species in the WWCR3 analytical dataset.

Across the four species groups recorded in seizure data, totalling 1,652 species, 40 per cent have been classified as threatened or Near Threatened species.
and a further 20 per cent of those classified as Least Concern have been flagged as experiencing a decreasing global population trend. Only the bird species diverge from this pattern significantly with a smaller proportion of the species recorded in seizures classified as threatened.12

Since this assessment does not take account of the volume of illegal trade inferred by seizures nor the actual causes of extinction risk for each species recorded, it should not be interpreted as a direct measure of conservation impact. However, it does demonstrate that wildlife crime involves a very wide range of species of conservation concern.

Using the same datasets, it is possible to probe the question of threat attribution in more depth. The IUCN Red List database also includes expert assessment of the significance of different threats that have contributed or still contribute to the conservation status and population trend of a species. Across the four species groups, around 50 per cent of the species recorded in seizures are identified in the IUCN Red List database as subject to ongoing threat from intentional harvest (Figure 3.3). For mammals the proportion is higher (73 per cent) and for birds it is lower (31 per cent).

Two difficult challenges frustrate deeper evaluation of the extent to which wildlife crime threatens individual species. First, seizure records alone only provide a partial insight into actual illegal trade levels. Second, conservation impact assessment would require knowledge of precisely where the trade originated, the number of individuals harvested to supply the trade, the age and gender of individuals harvested, when and how they are harvested, and a range of other factors related to population and habitat health. Moreover, the conservation status of a species often varies across its range so that illegal trade may have lower impacts in areas where the species is abundant than it has in areas where it is scarce.
Ecosystem impacts

The conservation harm caused by illegal wildlife trade is not only the overexploitation threat to the survival of a species. The decline in abundance of a species’ population also contributes to degradation of the range of functions and processes the impacted species provide in their ecosystems. These harms to ecosystem stability and resilience undermine their various environmental, social, and economic values. Interdependence between different species and overall ecosystem functionality is complicated and recovery from disruption is hard to predict. Wildlife crime affects a wide range of species with different ecological roles, so its ecosystem impact cannot be simply generalized. For example, poaching of big cats or other predators can lead to increased herbivore prey populations, leading to changes in grazing intensity that may alter plant diversity and overall ecosystem function. Conversely, poaching and excessive illegal trade in meat of herbivores that are a food source for big cats, although possibly not a conservation threat to the target species, may have a serious negative impact on predator populations. Other species targeted for illegal trade may play important roles in seed dispersal, as pollinators or in habitat structure. Disruption of ecosystems can reduce availability of the goods and services used by people and negatively impact associated soil and water resources.

Although ecosystem-level conservation is increasingly referenced in natural resource management policy and practice, harm to ecosystems is rarely designated as the primary threat that wildlife trade legislation is enacted to prevent. Nevertheless, there is a requirement to consider the role of species in their ecosystems as a pre-condition for regulated wildlife trade under Article IV of CITES, and a recent Food and Agriculture Organization of the United Nations (FAO) study noted there is a growing body of international, regional and national legislation requiring ecosystem approaches to fisheries and trade in fisheries products.

Climate impacts

Ecosystem disruption resulting from species over-exploitation driven by wildlife crime also has considerable potential to affect carbon storage and emissions and to undermine the critical role that natural ecosystems play in long-term climate stability and mitigation of climate change impacts. In 2022, a UNODC review of available evidence demonstrated that the pathway of cause and effect between illegal wildlife trade, species depletion, disruption of ecosystems, and processes that affect the climate is diverse, complex and not comprehensively documented (Figure 3.4).

A prominent negative impact of wildlife crime on carbon storage and emissions is its role in driving excessive removal of large-bodied species that store significant amounts of carbon, notably trees illegally harvested for timber. The level of impact depends on the characteristics of the tree species affected and the subsequent management of the impacted forest area, although corruption, illegal timber harvests and illegal trade typically undermine sustainable forest stewardship efforts.

There is an emerging body of research on potential climate impacts of population reductions of various species affected by wildlife crime. A recent study on forest-dwelling elephants in Africa examined their impacts as herbivores on forest structure and estimated that their removal through poaching or other threats could result in a 6–9 per cent decrease in the above ground carbon stocks in Central African rainforests. An economic analysis based on these estimates claimed that elephant poaching would result in $2–7 billion of lost carbon services within the next 10–30 years. Similarly a study of white rhinoceros, also threatened by poaching and illegal trade, showed positive impacts on soil carbon levels in grassland habitats in Southern Africa compared to domestic livestock. A simulation study on the impact of poaching of large-bodied frugivores in South-East Asia considered a reduction in seed dispersal led to a reduction in carbon storage in tropical forests. Greater clarity about climate-related impacts of wildlife crime is likely to emerge as further research on this topic is published.

It is critical to keep in mind that this relationship works in both directions: climate change is likely to exacerbate natural resource conflicts as human and wildlife populations adapt to evolving living conditions and people compete for increasingly scarce resources. Furthermore, climate change impacts, such as extreme weather, drought, floods, famine, and migration have been predicted to cause profound social changes that will provide fertile conditions for crime to proliferate. This will likely lead to new motivations and opportunities for wildlife crime and new patterns of illegal wildlife trade.
FIG. 3.4 Assessing impacts of illegal wildlife trade on species, ecosystems and climate

Wildlife trafficking

1. Is wildlife trade reducing wildlife populations?
2. Is there a significant direct loss of carbon storage?
3. Is there a significant detrimental impact on ecosystems?
4. Is there a significant indirect impact on the climate-relevant functions of ecosystems?

Source: UNODC research brief
Another important environmental harm potentially linked to illegal wildlife trade is the damage caused as increasing numbers of wild species are introduced by human activity outside their natural range. Sometimes such introduced species become invasive, causing negative and in some cases irreversible impacts on nature and natural resources upon which people depend. Wildlife trade has been identified as an important introduction pathway for dispersal of invasive alien species. Although not widespread, there are cases in which this concern has been specifically addressed through legislation governing wildlife trade, such as the European Union Invasive Alien Species Regulation, which provides for trade prohibitions for species at risk of becoming invasive, rather than the threat of their overexploitation.

A 2019 study found that the animal pet trade has already led to the establishment of several hundred non-native and invasive animal species globally and was likely to contribute to the establishment of more in the future. Likewise, a study of plant trade claimed that it was acting as an important pathway for introduction of invasive flora in the United States. However, these studies largely focus on legal trade as a pathway for introduction of invasive species. The specific harms from illegal wildlife trade in this regard have not been explored in depth although a study of the risks associated with illegal import of exotic live reptiles into Australia raised concerns about the potential negative impact on native fauna if these animals are released into the wild.

To explore this further, UNODC examined the extent to which known invasive alien wildlife species are recorded in recent seizure data. Seizures of live mammal, bird, reptile, and amphibian specimens recorded in the WWCR3 analytical dataset during the period 2015–2021 were examined to see if they concerned species listed as invasive in the Global Invasive Species Database. Some 83 species (6 per cent) of the 1,255 live species seized across the four species...
groups were flagged as invasive in the Database, the majority of them mammal or bird species (Figure 3.5).

While invasive species make up a small minority of all trafficked species, it appears that a significant proportion of invasive species are trafficked. The 83 live seized species represent 27 per cent of the 304 wild species from the four species groups examined that are designated as invasive in the Global Invasive Species Database. However, the significance of these results should be treated with caution as the seized invasive species include many animals, such as brown rat, red fox, wild boar, Canada goose, budgerigar and red-eared terrapin, already widespread outside their natural range. The subset of 48 of these traded and potentially invasive species that are subject to CITES trade controls are without exception also commonly recorded in legal trade. Nevertheless, this analysis does demonstrate that a wide range of known invasive species do appear in illegal trade, undermining monitoring and regulation efforts aimed to assess and address risks from the movement of invasive species.

**Social and economic harms**

**Well-being and livelihoods**

Species depletion and ecosystem disruption caused by wildlife crime can undermine the many benefits that people derive from nature. These include material contributions to livelihoods, such as food, medicines, and energy, as well as non-material contributions to identity, culture and learning, and the role nature plays in the environmental processes upon which life support systems such as agriculture and water supply depend. The IPBES *Global Assessment Report on Biodiversity and Ecosystem Services* stated that, since 1970, 14 of the 18 categories of nature’s contributions to good quality of life had declined (Figure 3.6).

Discerning the specific contribution of illegal wildlife trade to overall global declines in benefits to people from nature at a global scale is not straightforward. A World Bank 2019 study estimated long-term global economic losses associated with illegal logging, fishing, and other components of illegal wildlife trade of about $1–2 trillion per year, more than 90 per cent of this figure derived from the estimated value of ecosystem, regulating and cultural services that are not priced by markets. The study stressed limitations and uncertainties with the underlying data, but highlighted the critical message that, however quantified in economic terms, very significant benefits to human well-being and livelihoods may be undermined or lost because of wildlife crime. Loss of such benefits is seldom explicitly considered when legislation is designed, cost-benefit analyses are conducted, or when enforcement priorities, policies and implementation strategies are elaborated.

Importantly, although often overlooked, wildlife crime can also cause a range of cascading, non-monetary harms to human well-being associated with the various values that people place on wildlife. These include a range of cultural, religious and spiritual, historical, relational, and scientific values, as well as existence, intrinsic and bequest values for wildlife species that shape many human–nature relationships and are important constituents of human well-being. The IPBES *Global Assessment Report on Biodiversity and Ecosystem Services* specifically highlighted that recognizing these types of diverse values and ontologies in policies is key to delivering greater sustainability but is often dismissed in decision-making and policy systems dominated by economic rationale.

Harms to human well-being caused by wildlife crime extend beyond those related to income and access to resources. Other impacts can include reduced security, exposure to violence, undermining community cohesion, and increased vulnerability to abusive employment practices and human trafficking. Impacts of environmental degradation may be race, class and gender-differentiated; men and women may have different perceptions and experiences of the costs of biodiversity loss. Mounting evidence reveals that gender equality is causally linked with socioenvironmental well-being. A UNODC case study on gender dimensions in South America highlighted several vulnerabilities that women may experience in direct relation to wildlife crime. Women frequently take roles with the least power and greatest personal risk under conditions that men in similar positions rarely face. Conversely, men are more often exposed to violence.

**Private sector costs and losses**

Wildlife crime can have direct negative impact on economies by increasing costs and losses for private sector stakeholders, including businesses and both private and customary land holders. Those affected include operations engaged in legal wildlife trade, along with businesses providing trade facilitation services, such as banking, transport and marketing. The impact of such economic harm also extends to operations dependent on thriving wildlife populations, most obviously tourism operators and others gaining income from facilitation of wildlife viewing experiences.

Wildlife crime-related income losses for operations engaged in legal wildlife trade may result from reduced access to resources, unfair competition, and potentially also from sectorial reputational damage caused by association with illegal activities. Additional costs also may accrue from the need to identify and acquire alternative supply, to invest in legality verification and traceability systems, and from competition in the market with illegal actors.43,44,45

Assessing losses from wildlife crime to private sector tourism operations is not straightforward. The relationship between tourism motivations and the status of wildlife populations is complicated, with strong focus typically on a small number of species of interest in any location.46 Most analyses have a restricted geographical scope although one 2016 study carried out a continental assessment of the economic losses to tourism in Africa from the illegal killing of elephants.47 Annual losses to both public and private sector interests were estimated to be around $25 million, although it should be acknowledged that this is likely an atypical example owing to the prominence of this species in safari tourism.

**Health risks**

Disease risks associated with wildlife trade have regularly been flagged in recent decades by specialists in the human and animal health fields. Concerns are related both to direct risks of disease transmission to people from live animals and plants, wildlife meat and other products, and also to the threat to wildlife populations, natural ecosystems, livestock and agricultural food production systems.48 It had long been predicted that the expanding scope and volume of wildlife commerce as a component of the growing and increasingly interconnected globalized world economy increased the risk of emergence and spread of new dangerous diseases from animals to people.49 It is therefore not surprising that attention to this issue rose sharply in 2020 when early commentary on the possible origin of the COVID-19 pandemic suggested links to markets where wild animals were believed to have been on sale as pets and for food.50,51 Although subsequent research on the origin of the disease has not reached a definitive conclusion, a comprehensive evidence review published in late 2022 noted that most papers on this topic point to a zoonotic origin of the coronavirus.52

An IUCN situation analysis in 2022 examined evidence of the relationship between wildlife and emerging diseases and human pathogens, their origins, drivers, and risk factors.53 It concluded that the vast majority of such diseases and infections derive from domesticated animals or as a result of human disruption of natural habitats. For wildlife trade, the study found that evidence of human disease and pathogen emergence from trade in wild-sourced animals was sparse and restricted to a few events, though cautioned that this could simply reflect gaps in knowledge. Other reviews have noted evidence of significant levels of pathogen occurrence of public health concern in live animals and wildlife meat found in illegal trade, so risks of spillover to the human population cannot be discounted.54,55 The IUCN analysis urged improved surveillance of disease cases linked to wildlife trade and highlighted wildlife breeding operations and larger scale trade flows involving live animals and wildlife meat as priorities for pathogen monitoring. The report stressed that illegal trade posed particular risks, in part because it was likely to bypass health screening and control measures.56

Many countries have significant legal provisions aimed to prevent disease and infection from movements of animals, plants and their products. These include risk-based trade restrictions, quarantine, animal health and phytosanitary inspection in trade and in the marketplace. Such regulation is typically designed primarily to address risks from high volume production, trade and consumption from domesticated livestock and crops although their application is usually inclusive of wild animal and plant trade.57 Some
countries have adopted additional health-focused restrictions on specific types of wildlife trade. A prominent example is the European Union ban on import of live wild birds, first adopted in 2005 and amended in 2013 as a measure aimed to combat avian influenza.58,59

Potential and realized health-related harm has clear relevance as a consideration when assessing the significance of wildlife crime. Illegal trade by its very nature may be routed to avoid border inspections, quarantine and other control measures aimed to reduce health-related risks, making it more risky than legal trade. Examination of supplementary data in seizure records in the WWCR3 analytical dataset on the reason for confiscation and the agency making the seizure shows that many wildlife contraband interdictions involve contraventions of veterinary or phytosanitary regulations and enforcement action by animal and plant health inspection agencies. When legal and illegal trade channels intercept: in holding facilities, markets or because of laundering illegally supplied specimens into breeding or farming operations, there are added health-related risks.60

There are no simple metrics for assessment of risk or the impacts of such harm. One recent study based on seizure data assessed the presence in illegal trade of live animals of wild species associated with 11 priority diseases—known as the WHO R&D Blueprint priority diseases—that are considered by the World Health Organization (WHO) to pose the greatest public health risk owing to their epidemic potential and the absence of sufficient countermeasures.61 Species from 31 families of mammals, birds, and reptiles associated with the priority diseases were identified in global seizure data for 2011–2020. Important caveats were noted with respect to potential sampling and reporting biases for both species and pathogens; the fact that zoonotic spillover may not have been confirmed in all species/ disease associations included in the dataset; and that the study did not take into account variations in risk caused by differing conditions in rearing, housing, or transporting wildlife products. The study recommended that future exploration of this topic should include other higher risk commodity types (such as meat), trade routes, and estimated volumes of illegal trade, as well as the impact that factors such as concealment methods may have on spillover risk.

Harm to environmental defenders

Various roles embody the function of "environmental defender", including community defenders who do not hold the position as a technical profession. These environmental defenders can play a critical role in wildlife protection, including prevention of wildlife crime, but also can be victims of harassment, violence and in some cases, loss of life.62,63,64 A direct manifestation of the harms of wildlife crime is injury to and loss of life of people engaged in wildlife protection. The International Ranger Federation’s annual roll of honour of wildlife rangers who are reported to have lost their lives in the line of duty recorded a total of 2,351 deaths between 2006–2021, over 80 per cent of them in Africa and Asia.65 Felonious deaths including homicides made up more than 40 per cent of the total ranger lives lost, with causes for the remainder including vehicle and aircraft accidents, firefighting, drowning, illness and others. Many other fatalities are not recorded and there are no comparable data on non-fatal injuries, which in some cases may lead to permanent disability, nor on other harms, such as intimidation and harassment. Risks were reported to be exacerbated by a range of factors, including remoteness of work locations, conflict-derived firearm availability, inadequate first aid training, and poor living conditions.66

Women and men rangers and other environmental defenders have distinct experiences of harm on the job, and for women many of these conditions are doubly challenging as they often additionally face hostility from male colleagues. Similarly, women and men in many defender positions, notably community defenders, face considerable threats that distinctly reflect gender differences.67,68

Although less well-documented, threats of physical harm and other forms of coercion are risks at other levels of the criminal justice system, including police, customs officials, prosecutors and the judiciary.69,70 Such threats are often linked to corruption, as explored in chapter four.
Governance harms

Undermining the rule of law

As a globally significant crime sector, illegal wildlife trade raises concerns about its negative impacts on the robustness of government institutions. As with other forms of criminality, wildlife crime undermines the rule of law and functions of government institutions through corruption, money-laundering, illicit financial movements and cross investment between crime sectors. Although these are generally difficult issues to assess systematically, there is a growing body of work examining their relationship to wildlife crime.

Loss of government revenues

As in other sectors, one potential harm of wildlife crime is the loss of government revenues, particularly those of source countries. Usually payable through legal harvest and trade licence fees and taxation, these can represent significant losses to national economies. However, they can also involve losses such as tourism revenues, which in some contexts are significant to local and national economies and key elements of funding conservation. A 2019 World Bank report estimated that governments lose $7–12 billion per year in potential fiscal revenues from illegal logging, fishing, and other wildlife trade. This was based on estimates of both direct taxation and user fees that might have been paid if the same trade had been carried out legally. It also includes some estimation of lost indirect income from taxation of tourism if visitors are deterred by reductions in wildlife populations or security concerns linked to illegal trade.

Another recent study focused specifically on illicit trade in marine fish catch and estimated global losses to tax revenues of $2–4 billion, affecting maritime African and Asian countries much more than other parts of the world.

Lost revenue estimates rely on assumptions that are difficult to test in practice, and wildlife crimes vary. As illustrated in previous editions of the World Wildlife Crime Report, while some exclusively involve illegal transactions along their value chain, other goods may enter the legal market at some stages of the supply chain (for example through falsified documentation or laundering operations), and so some user fees and taxes may be paid even within wildlife trade flows that are illegal at some point along their course.

Financial costs of enforcement

The prevalence and importance of wildlife crimes have necessitated increased public and private investments into conservation, law enforcement and other criminal
justice functions globally. Financial costs can be substantial and tend to be borne largely by government budgets, potentially diverting funds from other uses.

Few estimates of the financial costs of enforcement action to address wildlife crime have been published, but they can be significant especially in the context of developing economies. A national study in Namibia estimated in 2021 that expenditure required to curb illegal wildlife trade in the country was about 250 million Namibian dollars (US$17 million) per year.79 A report on expenditure on protecting rhinoceros species from poaching and illegal trade in the Greater Kruger Region of South Africa estimated that interventions had cost 1.1 billion rand (US$61 million) over the period 2017–2021, with the majority spent on security staffing, fencing, air support, detection technology, and access control.80

Significant investments from partner governments, foundations and non-governmental organizations (NGOs) have been made to support such government efforts through provision of training, equipment, and technical support. A World Bank review of international funding committed to combat illegal wildlife trade during 2010–2016 estimated annual investment by donor agencies of about US$190 million a year globally.81 Updated figures are planned for publication by the World Bank in 2024.

**Harms from wildlife crime responses**

Some harms result from responses to wildlife crime, rather than the crime itself. Criminal justice systems are normally designed to inflict higher penalties on those who commit higher levels of crime.82 However, there has been no comprehensive assessment to date of whether criminal justice system impacts on wildlife crime perpetrators is proportional across different jurisdictions and different population groups. Indeed, there is mounting evidence from studies in different countries that lower-level participants are disproportionately targeted for criminal enforcement in comparison to higher-level participants and those operating across jurisdictions.83,84

There is also a growing body of research aimed at understanding—through offender interviews and other methods—the circumstances in which people in the earliest stages of the trade chain become involved in wildlife crime and the socioeconomic consequences of detection. Findings from Nepal and Southern Africa show that many offenders are imprisoned for participation in activities that were not the primary source of their livelihoods. Offenders often claimed to have underestimated the risk of detection and serious sanctions and reported very serious negative impacts on family well-being resulting from their incarceration.85,86,87

As part of the research for the current report, a study was initiated by UNODC to gain additional insights from convicted wildlife crime offenders in Indonesia.88 Preliminary findings mirror those from elsewhere: many of those incarcerated appear to have been low-level participants in poaching and delivery of illegal wildlife goods. The majority claimed it was their first involvement and they had been motivated by the opportunity to gain additional income to their main livelihood. Although most offenders admitted to knowing that they were participating in illegal activity, again the social impacts of incarceration in terms of reputation and employment appeared to have been discounted.89

The social impacts of law enforcement may be gender differentiated. Most imprisoned offenders are men and their removal from households can leave female-headed households in economic instability and facing other types of insecurity. Preliminary evidence suggests that women and men are treated differently in wildlife trafficking enforcement—women may be overlooked or not taken seriously as (possible) offenders.90

Similarly, other stakeholders can face increased costs in dealing with wildlife crime responses. For example, businesses providing trade facilitation services risk potential legal liability if implicated in facilitating illegal wildlife trade. In the banking sector there is an increasing focus on the imperative to apply money-laundering controls to obstruct financial flows arising from wildlife crime in line with Financial Action Task Force standards and related national compliance measures.91,92 Although sectoral initiatives to prevent wildlife crime in the transport and online commerce sectors do not articulate loss avoidance as a primary motivation, concern about business risks is at least implicit in the public promotion of their actions.93
Accounting for wildlife crime harms

This chapter aimed to take stock of the diverse harms associated with wildlife crime and to examine available evidence on their extent to inform considerations of their significance and the prioritization of responses. It also considers how additional harms can be caused by the responses aimed to reduce wildlife trafficking.

Although instances of illegal wildlife trade may contravene legal measures aimed to reduce different environmental, social and institutional harms, the predominant institutional framing of wildlife crime concern remains the conservation-focused policy and law aimed to prevent the overexploitation and extinction risk to wildlife species. The cascade of harm described in this chapter is rarely represented in legislation, policy or enforcement responses. On the contrary, legal and policy responses are typically associated with administrative and criminal sanctions to stop and punish harm (e.g. fines, imprisonment, removal of permits). Although such responses are important, such mainstream approaches often overlook the importance of providing remedies to harm.

Better accounting for harms will likely challenge many mainstream enforcement priorities and practices. For example, there has been a strong focus on illegal trade flows affecting high-profile species, such as elephants, pangolins and rhinoceroses. This emphasis is likely reflected in the frequent occurrence of products from these species in the seizure records summarized in chapter two of this report. However, analysis in the current chapter makes it clear that illegal trade involves a wide range of threatened wildlife species and reveals a greater range of types of harm. Better recognition of and accounting for diverse types of harm could improve recognition of risk and inform priority-setting.

Similarly, enforcement may be guided by perceptions about crime, notably measures of criminality are often associated with their monetary value. This leads to a focus on illegal wildlife trade expected to afford the greatest profits to criminal organizations, those linked to conflict and security concerns, impacts on government revenues, or convergence with other crime types. Although these can be important variables on which to set priorities, they are often difficult to define and measure and there is a tendency to fall back on metrics such as gross valuation of trade flows.

There is tension between these two generalized perspectives on harm from wildlife crime. Some of the most dangerous illegal trade flows from a conservation perspective may involve quite small numbers of individual animals or plants that are highly threatened and for which such illicit commerce has a genuine risk of driving a species towards extinction. However, the monetary value and the obvious social and institutional harms associated with such trade are likely small compared with those related to other trafficked species. If there is a solution to this disconnect between different classes of concern, it is likely to be through greater attention to the interdependence between environmental, social and institutional factors. Accounting for wildlife crime harms requires policy broadening, improved communication and exploration of broader legal tools that can hold offenders responsible for remedying the harms they cause.

11 See https://www.iucnredlist.org/ for species data and explanation of status and threat categories.

12 The IUCN Red List Categories indicate the conclusion of evaluation of how close a species is to becoming extinct. Threatened species are those classified as Critically Endangered, Endangered or Vulnerable. Species classified as Near Threatened are judged to be close to qualifying for or are likely to qualify for a threatened category in the near future, Species classified as Least Concern have been evaluated and found not to meet the threatened or Near Threatened criteria although some may have declining populations.

18 Article IV paragraph 3 of CITES states that “A Scientific Authority in each Party shall monitor both the export permits granted by that State for specimens of species included in Appendix II and the actual exports of such specimens. Whenever a Scientific Authority determines that the export of specimens of any such species should be limited in order to maintain that species throughout its range at a level consistent with its role in the ecosystems in which it occurs and well above the level at which that species might become eligible for inclusion in Appendix I, the Scientific Authority shall advise the appropriate Management Authority of suitable measures to be taken to limit the grant of export permits for specimens of that species”.

Chapter 4

Drivers
The driving forces behind wildlife crime are a complex interplay of motivations and influences, from economic incentives to socio-cultural dynamics. This chapter attempts to shed light on the diverse drivers shaping the patterns and trends of criminality connected with wildlife trafficking. Better understanding of these factors can inform the design and refinement of remedial interventions.

The approach taken is to consider motivations and influences at three stages of the trade chain: drivers of sourcing, drivers of illegal trading and drivers of demand in end markets. The following three sections of this chapter are structured to take stock of evidence about factors driving participation in crime at each of these stages. A fourth section considers the role of corruption as an enabling factor and a force undermining measures aimed to reduce illegal wildlife trade along the trade chain (Figure 4.1).

Although it is informative to consider the distinct motivations and influences for participants at different stages of the trade chain as well as the system-wide enabling role of corruption, it is important to keep in mind that these elements are interconnected. This has been described as a wildlife crime continuum in which successful crimes by individuals and organizations at different steps along the trade chain provide opportunities for other crimes. Participants each have something to offer and to gain while precise roles and relationships are context and time specific and likely to evolve.1
Drivers of illegal sourcing

**Context**

Wildlife trafficking differs from some other forms of transnational organized crime in that the primary harm occurs up front, in the country from which the wildlife is sourced. This is different from the trade in illicit drugs, for example, where the primary concern is the prevention of health-related harms to end users, so stopping it anywhere in the trafficking chain prevents that harm from being realized. In contrast, the principal conservation harm that wildlife trade laws are designed to prevent has already occurred when animals or plants are removed from the wild. Any interdiction that occurs after this action mainly serves as a potential deterrent to future trafficking, the impact of which depends on visibility and hard to predict shifts in market incentives. For this reason, understanding the driving factors behind the decision to source wildlife illegally is vital to its protection.

In the source country, someone needs to harvest or collect the wildlife and pass it on to someone else who has the capacity to sell it within the same country or internationally. There are some markets where the harvester is also the trafficker or the consumer, like the example described in a case study in chapter 6 of this report, where orchid collectors may organize expeditions to harvest rare or novel orchid species. However, these cases are exceptional and more typically the sourcing of wildlife entering illegal trade is carried out by a distinct group in the trade chain.
Organized commercial illegal sourcing

Clearly there are some people who deliberately and professionally poach or illegally harvest wildlife for profit. Sometimes they are specialized poachers or collectors not from the local area. Evidence of rhinoceros and elephant poaching in Africa reviewed in the case studies for the current and past editions of the *World Wildlife Crime Report* has indicated the involvement of remotely directed and equipped mobile poaching gangs. Similar structures have been documented for poaching of tigers in Indonesia and abalone in South Africa.4,5

The industrialization of highly profitable illegal wildlife sourcing is best exemplified in the fisheries and timber trade sectors. In the fisheries trade sector, illegal operators often use flags of convenience and complicated multi-jurisdictional business ownership networks to avoid exposure to law enforcement.6 Profits from a wide range of fisheries have been demonstrated to attract involvement of organized crime groups.7 Research based on interviews with officials in Mexico revealed that organized crime groups in the country had infiltrated both legal and illegal fisheries trade chains, with significant control over illegal fishing operations.8 Similarly, in the timber trade sector profits from illegal logging have attracted significant corporate engagement although it appears that the involvement of small-scale producers was increasing during the 2010s as larger companies experienced increasing regulatory and market pressure.9

Additional examples of convergence between wildlife trafficking and other criminal businesses have been noted in chapter 2 of this report. Such connections have been shown to enable wildlife trafficking through power relationships with local communities, corrupt relationships and opportunities for money-laundering. They may also provide access to illicit firearms, ammunition or other tools that aid illegal wildlife sourcing directly, for killing target species, and indirectly, for protection and intimidation of other actors in the trafficking chain.10

Supplementary livelihoods and opportunism

Sometimes illegal harvest is predominantly carried out by local people who live alongside wildlife every day, often drawing their livelihood from nature in other ways. Such harvesters may live in communities remote from urban centres, with limited state presence. They may have few opportunities to earn cash income and the emergence of demand for wildlife from their area, manifested by trader offers to purchase, may represent a kind of windfall. The interest of different groups may coincide even at a local level, with specialized poachers and collectors enlisting support and involvement of local community members to aid their activities.

Poverty may be a driving factor in the decision to poach for some, but poachers may not necessarily be acting in desperation. A study of prisoners in Nepal found that those incarcerated for crimes related to wildlife trafficking comprised between 10 per cent and 20 per cent of the overall prison population in the two regions studied.11 Most of the 384 prisoners in the study who had been convicted for offences related to wildlife trafficking were poor (56 per cent) and from indigenous communities (75 per cent). Of the 116 prisoners individually interviewed, all but one being male, most said that their involvement in wildlife crime was simply an easy way to make extra money. The study concluded that illegal wildlife trade in Nepal was neither a primary livelihood strategy, nor formal organized crime.

Two research studies in Southern Africa involving wildlife crime offender interviews in Namibia and South Africa showed similar findings. The South Africa study involved interviews with 73 offenders incarcerated for offences related to wildlife trafficking, including poaching and illegal trade in abalone, cycads and rhino horn.12 Most were low level participants in poaching, transport or processing and many were from marginalized communities who were either unemployed or informally employed, with little access to alternative economic opportunity. The Namibia study involved interviews with 45 male offenders incarcerated for offences related to wildlife trafficking. Most of the offenders were low-level poachers or traders within the supply chain with limited knowledge of the market they were supplying. They were either fully or partially employed, mostly in agriculture, but engaged in poaching/trading occasionally and on an opportunistic basis.13
Similarly, a survey of convicted wildlife crime offenders in prison in Indonesia conducted by UNODC for this report found that out of the 11 interviewees self-identified as poachers, all male, only one appeared to be regularly occupied with such activity. Rather, most were small-scale farmers with fields abutting wildlife areas, some of whom hunted non-protected wildlife. About half of the poachers interviewed (five out of eleven) claimed not to know what they were doing was illegal. The other half typically came across a chance opportunity to earn some cash for their families and took it knowingly.

Their situation is similar to that of the fishers interviewed in Peru for the illegal seahorse trade case study in chapter 6 of this report. Peruvian fishers may find seahorses tangled in their nets as by-catch when targeting other fish species. Usually dead or dying, returning these animals to the sea may seem pointless to the fishers, while retaining them requires very little additional effort. The choice to capitalize on wildlife that is already lost at the time encountered may not be a difficult one for people who make their living from nature. Of course, those who buy the seahorses and sell them to international traffickers have gone beyond simple opportunism. Consolidators active within the Peruvian seahorse trade chain appeared to be among the wealthier community members and/or owners of small businesses who had the means to transport wildlife to urban centres.

People and wildlife in conflict

Opportunistic engagement in illegal wildlife sourcing sometimes occurs in the context of human-wildlife conflict. For example, one prisoner interviewed in Indonesia during the aforementioned UNODC survey reported helping a neighbour poison an elephant that was destroying crops and then taking the ivory in the hopes of making some money on the side. Another offender reported that his community had installed an electric fence to stop elephants from raiding their crops and collected ivory from three of the five elephants that died as a result. Yet another caught a tiger in a snare intended to prevent wild pigs from eating his rice crop and collected the bones after the tiger had decomposed, finding a buyer for them over a year afterwards. Many claimed it was their first time handling protected species and that they were caught through enforcement sting operations.

Perceptions of legality

Part-time participants in illegal wildlife sourcing are not alone in claiming ignorance of the law. It appeared from interviews carried out for the rosewood case study in chapter 6 of this report that the effect of national legislation and regulatory measures was not always clear to participants in the timber industry in Nigeria. Although timber in rough or sawn form has long been on the Nigeria Customs list of banned exports, the CITES Management Authority of Nigeria issued permits for the export of many containers of rosewood in 2017 and 2018. Timber harvesting in Nigeria is largely governed at the state level and there are 36 states and a federal capital territory, each with its own set of forestry laws, most with little enforcement capacity. By the time the timber reaches port it is very difficult to determine whether a particular piece of timber was harvested legally or not. As a result of this complexity in applicable legal provisions participants, even at the supply side of this market, may not always have been aware when they were involved in illegal trade.

From legal to illegal

The rosewood case study in chapter 6 of this report illustrates how participants in well-established wildlife trade sectors may fail to adapt to regulatory changes and try to sustain what has become an illegal business. While lamenting the loss of trees, the local traditional leaders interviewed for this report in Taraba State, Nigeria, expounded the benefits that the rosewood trade had brought to their areas. They said it had reduced crime generally within their communities by providing employment to the youth. The trade was “taxed” by many formal and informal authorities, distributing the benefits to hundreds of families. It allowed the growth of infrastructure—including the construction of sawmills and lumber depots, the purchase of specialist vehicles and cranes, and the accumulation of skills. Many of the timber trade workers interviewed spoke of the losses suffered when the rosewood legal exports abruptly ended owing to CITES compliance concerns, but the benefits in one of the country’s
poorest states had been significant and motivation to sustain involvement in this business, inside or outside the law was considerable.

**Tradition**

Financial incentives aside, involvement in illegal wildlife sourcing can also be driven by cultural tradition. Research in the periphery of Chinko reserve in the east of the Central African Republic found that some of those involved regarded elephant hunting as part of their cultural identity, a mark of bravery and manhood, a tradition that was passed between the generations. One of the largest threats to local communities was reportedly conflict with a group of men from the Sudan, who annually took a break from their cassava farms to go on an international hunting expedition, sometimes travelling over 1,000 km on horseback to find elephants to shoot. These Sudanese men were said to have hunted with spears until the 1980s and while they had switched to automatic weapons, the motivation apparently remained largely cultural, not profit driven.22

**Drivers of illegal trading**

**Context**

Both harvesters and consumers may participate in the illegal wildlife trade unwittingly, but with limited exceptions traders illegally buying, transporting, processing and selling wildlife along the trade chain do not. Smuggling wildlife requires knowing participation in the illegal market. Without illegal traders, the sources of supply and demand would never meet. In a sense, it is the illegal traders who individually or in combination help connect the illicit market, drawing revenues from the steps they manage along the trade chain and making the connections from the place of supply to the place of demand and actively working to ensure that associated business remains viable.

The exceptions are people or businesses trading wildlife wholly in ignorance of relevant laws, likely as tourist souvenirs or manufactured goods. Although not the focus of this analysis of drivers of wildlife crime, such participants may be responsible for a significant proportion of wildlife seizure incidents in some countries. For example, a review of seizures made by European Union countries in 2019 showed that over 25 per cent were packaged medicines containing wildlife ingredients or pieces of coral, typically carried in personal baggage.23 It is not known what proportion of these air passengers were aware that they were breaking the law.

**Specialized roles**

Illegal trading roles vary in terms of scope of engagement and influence along the trade chain.24 Some participants may act as local consolidators of illegally harvested wildlife goods before onward sale to urban centres or export markets, perhaps with limited insight into demand-side developments. Others draw profit from handling discrete roles, such as export, import, brokering, storage, keeping and breeding live specimens or handling the interface with processors. Case study examples in chapter 6 of this report and previous editions of the World Wildlife Crime Report highlight the key role that local consolidators play within source countries, channelling goods into onward trade chains. The same evidence sources show another phenomenon for illegal wildlife trade bridging continents: the involvement in trafficking chains of people from end market countries who arrived in source countries as workers in industries such as forestry, mining and infrastructure development. Later in the trade chain, there may be specialist wholesale and retail dealers with a good understanding of the end market but potentially with limited insight into supply-side factors. For some commodities various roles may be merged, with international traffickers handling multiple steps along the trade chain.

**Shaping market opportunities**

It would be oversimplistic to characterize all illegal wildlife traders as simply connecting those sourcing wildlife with existing end markets. In addition to managing steps along the trade chain, there is evidence that traffickers can play an active role in manipulating demand in end markets to sustain or expand business opportunities. Some products have been reinvented for different markets repeatedly. For example, rhinoceros horn was highly sought after in the 1980s for two purposes: as traditional medicine in various countries in East Asia and for the handles of traditional
daggers in Yemen. Rhinoceros horn as a medicinal ingredient has been banned in China since 1993 and around the same time a proclamation was made forbidding its use in Yemen. Illegal trade flows steeply fell and it was not until the mid-2000s that rhinoceros horn was again marketed, this time in Viet Nam for a variety of purposes, including cancer treatment and as a remedy for the effects of excessive alcohol consumption.25 As demand for consumptive use in Viet Nam has apparently fallen in recent years, as evidenced by price decreases, it has again been remarked in the same country in the form of collectible decorative items, including libation cups, bangles and beads.26

The emerging market for jaguar canines and claws may be similar, created by traffickers due to the availability of supply from animals killed for livestock protection, not pre-existing demand. Unlike Asian and African big cats, jaguars have not historically been exploited in the main destination markets in Asia. Although there is some circumstantial evidence of emerging export trade, a CITES review of jaguar trade concluded that most demand for jaguar parts was local within range states, where teeth and claws were being marketed as souvenirs and trinkets.27 The complexities of trafficking connections between supply and demand for the trade in big cat bones are explored further in Box 4.1.

**Tactical adaptation**

In addition to pushing their products actively, illegal traders also engage in corruption and undermine the rule of law in countries along the trafficking chain, which appears to be essential to moving products along transport routes and across controlled borders predictably. A review of evidence of financial flows and payment mechanisms from over 40 wildlife crime cases in Africa, Asia and Latin America found bribery of officials to be a common tactic, particularly the procurement of false documents and arrangements to avoid shipment inspection.28 Opportunities to secure safe passage for illegal goods through corruption can have a significant impact on how smuggling routes are established and how they adapt over time.29

Where corruption does not work, illegal traders find other ways around law enforcement. Most trafficked species are available from several countries, so good enforcement in one may compel illegal traders to switch sourcing and operate out of another. Illegal traders also take steps to reduce risk exposure, changing shipment routing to avoid law enforcement scrutiny along direct or exposed trade routes. For example, from about 2018 there was a series of prosecutions of elephant ivory traffickers in East Africa that appears to have influenced illegal traders to switch to exporting ivory from the other side of the continent entirely.30 Between 2010–2015, the weight of tusks in seizures made in or intercepted from Kenya and the United Republic of Tanzania dwarfed those connected with Nigeria and the Democratic Republic of the Congo. Between 2016–2021, the reverse was true (Figure 4.2).

Both sourcing and routing shifts in response to enforcement action have been observed in elephant ivory trade and rhinoceros horn trade patterns analysed in previous editions of the *World Wildlife Crime Report* and documented in regular CITES reports on these commodity sectors.32 Together these shifts in sourcing and trafficking routes have been characterized for other illegal commodities as a balloon effect, where an enforcement squeeze in one place leads to a bulge elsewhere, with a resulting spread of related harms.33
The five big cat species classified as members of the *Panthera* genus (jaguar, leopard, lion, snow leopard and tiger) range variously in Africa, Asia and Latin America and have long been subject to harvest pressure for trade in their parts for local and international markets. The *World Wildlife Crime Report 2020* examined in detail the poaching, trafficking and consumption of tiger bone, mostly destined for medicinal use in Asia. It also touched upon wider concerns about trade impacts on jaguars and lions, including issues related to big cat bone trade and the use of other body parts, such as skins, teeth and claws.

The complexity of supply and demand factors for big cats provides insights into the serious challenges of understanding and addressing drivers of wildlife trafficking. All five species have declining wild populations, all but the jaguar are classified as threatened in the *IUCN Red List of Threatened Species* and all but the lion are listed in CITES Appendix I. Trade is a key driver of poaching, but killing of these species is also often driven by human-wildlife conflict motivated by threats to livestock and people. Nevertheless, even in cases where trade was not the prime motivation for killing big cats, carcasses provide a tempting source of potential income if buyers can be found.

Since the early 1990s, there has been a steady increase in interest in development of captive-breeding operations, or farms, oriented in part towards commercial production of both tigers and lions for trade. Investors saw an opportunity because of dwindling supply from wild sources caused by a combination of population declines, hunting bans and increasing restrictions on commercial international trade from wild sources. CITES generally allows commercial international trade in listed species from farming or captive breeding with different regulatory requirements than those applied to trade from the wild, even for species in Appendix I, the strictest level of CITES protection. Furthermore, if breeding operations are in a consumer country, domestic trade is outside the mandate of CITES regulation.

There are CITES-listed species for which legal trade from commercial breeding operations is now the dominant source of supply to international markets. Examples include crocodile and parrot species, many listed in CITES Appendix I, like most big cats. However, CITES parties have consistently agreed a precautionary and restrictive stance on commercial tiger breeding for trade and expressed concern about the risks to wild populations from legalizing end markets.

At a national level, policies and legal measures governing development of big cat breeding operations and sales and use of big cat parts vary from country to country.

Several studies have been published in the last few years, particularly under the auspices of CITES, that document the persistence of markets for jaguar parts in South America, for lion parts within Africa, and a diverse range of big cat parts in Asia. These sources show that developments in the market for big cat bones primarily destined for medicinal use in East and South-East Asia are a common concern across all regions. Medicinal demand mainly focuses on the use of tiger bone, but overt or covert substitution of bones from other big cat species is not uncommon, whether simply to bolster supply, to confuse regulators or to diversify the offer to consumers.

From the early 1990s, for over a decade, supply of big cat bone to medicinal trade was increasingly restricted to use of old stocks, sourcing from poaching and, despite some ambiguity about sales restrictions, what is best characterized as leakage from tiger farms in contravention of national law. However, during the 2010s, South Africa permitted the legal export of lion skeletons to South-East Asia sourced from captive populations established by the sport hunting industry. A published analysis of export records from South Africa and reference to more recent CITES trade records indicate that as many as 7,500 lion skeletons, weighing over 80 tons, were legally exported from South Africa to South-East Asia between 2008–2018. Peak exports in 2014 and 2016 were over 10 tons per year, mostly destined for the Lao People’s Democratic Republic and Viet Nam. However, South Africa suspended issuance of export permits in 2019 and the Government of South Africa has since indicated its intention to end the captive lion breeding industry, setting up a ministerial task team to develop exit strategies to negotiate the closure of the industry.

Without greater insights into levels of annual consumption of end products, the extent of market control by pivotal traders, or trends in stockpiling of bone from these legal lion bone imports, it is difficult to assess how big cat bone trafficking incentives might be affected. A UNODC review of market data indicates that wholesale prices for unprocessed tiger and lion bone in one end market country were fairly consistent between 2018–2021. Consumer research in end
BOX 4.1 (continued) Big cat trafficking for the bone trade

markets suggests that various forms of medicinal demand are persistent and almost always gender-differentiated.\(^4\) Unless this changes, potential trafficking developments to watch for include:

**Sustained and diversified sourcing pressure on wild populations:** long-term analysis of seizure records shows consistent trafficking of wild-sourced tigers and their parts with skins most prevalent, but also for the bone trade.\(^5\) A CITES overview of big cat trade noted incidents of lion and jaguar poaching that may be destined for the bone market.\(^6\) A study of lion poaching and trade in the United Republic of Tanzania and Mozambique concluded that local use predominated in the United Republic of Tanzania, while in Mozambique poaching was assessed to be high with further evidence of domestic, regional, and international trade of lion parts and derivatives found to be occurring.\(^7\) However, for both these species and leopards, seizure records do not confirm high levels of bone trafficking from wild populations. In light of the recent drop in availability of large quantities of lion bone from captive sources there is a risk that this could change.

**Increased leakage of bone stocks held by tiger or lion captive facilities in Asia and Africa:** with over 12,000 tigers in captive facilities worldwide and around 8,000 lions in captivity in South Africa alone there is potential accumulation of carcasses and body parts from deceased animals.\(^8\) Leakage and intentional trade of such parts from tiger farms already contributes to bone trafficking flows and with the cessation of legal lion bone exports, there is a clear risk of similar problems. Twelve boxes of lion bones were seized in South Africa in 2019 reportedly prior to shipping to Malaysia,\(^9\) and there was a significant seizure in Viet Nam in 2021 of 3.1 tons of lion bone from South Africa shipped along with 138 kg of rhinoceros horn.\(^10\) These examples may indicate that farmed stocks stranded at source are being sought by traffickers. An ongoing CITES review of facilities holding Asian big cats includes attention to security measures for parts from deceased animals.\(^11\) A recent regulatory review raised concern about the absence of a lion bone stockpile register in South Africa at either a provincial or national level.\(^12\)

**Shifts in market structure:** at present it appears that most processing of big cat bones into medicinal products takes place in end market countries, with high value placed on demonstrating the authenticity of raw materials.\(^13\) However, there are some early indications of a possible trend to processing closer to source into products that may be easier to traffic, particularly paste or glue, made by boiling bones in hot water and eventually used in crude form or as an ingredient in medical preparations. There is evidence of such processing of lion bone in South Africa according to a 2018 national police report,\(^14\) and jaguar bone in Suriname according to academic research carried out in 2017–2018.\(^15\) It is currently unclear whether such production is primarily for domestic use by locals or expatriates from Asia, or destined for export, but it does represent a potential trafficking innovation to keep under scrutiny.

---

a. Other cat species, including the clouded leopard, cheetah and puma are also included within some analyses of big cat trade issues, for example CITES, ‘The Legal and Illegal Trade in Big Cats: A Study in Support of Decision 18.246. CITES SC75 Doc. 13 (Rev. 1)’ (Geneva, Switzerland: CITES Secretariat, 13 November 2022), https://cites.org/sites/default/files/documents/E-SC75-13-RT.pdf.

d. African lion populations are listed in CITES Appendix II, with the Indian population listed in Appendix I.

e. CITES, ‘The Legal and Illegal Trade in Big Cats: A Study in Support of Decision 18.246. CITES SC75 Doc. 13 (Rev. 1)’.

h. CITES Decision 14.69, adopted in 2007, states that “Parties with intensive operations breeding tigers on a commercial scale shall implement measures to restrict the captive population to a level supportive only to conserving wild tigers; tigers should not be bred for trade in their parts and derivatives”. Also CITES Resolution Conf. 12.5 (Rev. CoP19), on Conservation of and trade in tigers and other Appendix-I Asian big cat species, recommends that consumer States work with traditional medicine communities and industries to develop and implement strategies for gradually reducing and eventually eliminating the use of Asian big cat parts and derivatives.

n. CITES trade database https://trade.cites.org/.

q. UNODC reviewed price observation data for unprocessed tiger and lion bone in Viet Nam provided by Environmental Investigation Agency. There was no major change during 2018–2021, with tiger bone on average offered at a price 15-20 per cent higher than lion bone.

An additional tactical adaptation that may occur in response to enforcement pressure is to restructure the trade chain, for example by moving processing upstream so that goods traded illegally across international borders are in forms that may be less easy to detect. Police investigations in South Africa in 2017 discovered small home-based workshops in the country for processing rhinoceros horn beads, bracelets and bags of rhinoceros horn powder, apparently to avoid the risks of shipping unprocessed rhinoceros horn to end markets where such processing was usually carried out.34

### Cutting corners

It is notable that seizure records frequently include illegal transactions that appear from the available information to have been possible to carry out within the law. As noted above, there are doubtless cases where those responsible were ignorant of legal restrictions, but others likely reflect misguided expedience. Contributory factors are not well-researched but might include the desire to skip time-consuming administrative processes or to avoid taxes and licence fees. For example, in research for the illegal orchid trade case study in chapter 6 of this report, some of the buyers interviewed said that the costs of taxes, phytosanitary compliance certificates, and CITES documentation could exceed the value of the quantity of plants they wanted to import. They alleged that the orchids were trafficked not because they were from an illegal source, but because the hassle and cost of compliance were deemed too high. There are seizures of species that are cultivated commercially, but which it seems likely were being smuggled simply because this was commercially expedient.

### Supporting roles

Involvement of people in the trafficking chain is not restricted to those engaged in buying, transporting and selling wildlife illegally. Other participants may own or be employed in breeding operations: either breeding species in contravention of national law or laundering smuggled wildlife into ostensibly legal supply chains. Additionally, people may own or be employed in processing operations involved in functions such as carving, furniture manufacturing or food processing that use traded wildlife as raw materials, some of which may be illegally sourced.

Like traders, the principal motivation for involvement may be employment and income generation and at this point in the trade chain, their work may be within legal operations. As illustrated by the rosewood case study in the current report, regulatory change can leave large numbers of people with knowledge and skills related to wildlife trade seeking alternative employment, some of whom might be tempted into illegal activity.
Gender norms and roles shape individuals’ participation in wildlife-based economies, both legal and illegal. Men and women have different experiences of and access to wildlife, and notions of masculinity and femininity determine, at least in part, their motivations, willingness, and opportunities for participation in wildlife crime. These gendered realities affect who engages in wildlife crime and their roles within it.

To gain deeper understanding of gender-related dimensions of wildlife trafficking drivers, in 2023 UNODC carried out research in the Amazon regions of Colombia, Ecuador and Peru in South America. Interviews were carried out with wildlife trade participants who made observations at different points along the illegal wildlife trade chain in each country."a

Some the trade chains in the region encompassed familial structures. The research revealed a clear pattern where the involvement of one family member in illicit wildlife trade extends to others in the family. A common pattern was that wives or female partners (or other family members) of male poachers were reported frequently to engage in supplementary roles, helping to process, care for, transport, and/or sell the wildlife. Research has shown that women’s engagement in serious organized crime activities is typically initiated or inherited through a relationship with a father or husband involved in these activities."b According to one of those interviewed:

“No, women don’t go to the forest, but not because they are scared of the animals, it’s the men. The forest is dangerous because of people.”

Transportation

Women were notably more engaged in the transport of illegally sourced wildlife. It was reported that women and children are used in transporting illicit wildlife on roads and rivers coming from the Amazon region because they are seen as less conspicuous. According to one interviewee:

“I’ve seen women and children on the rivers, taking and bringing [illegal wildlife]. They are starting to use children more, I think.”

This tactic leverages societal perceptions of gender and age, revealing a calculated driver behind the roles assigned within the illegal wildlife trade. Other regional studies have also shown women having pronounced involvement in transport of illegal wildlife in the Congo and Viet Nam."c,d

Processing, preparation, storage

Processing and preparation of wildlife products was seen as a role mainly for women, but this was not consistent across all trade chains. For instance, medicinal products derived from wildlife (e.g. oils, salves, creams) were reported to be processed in the forest by men and brought into the markets already packaged and ready to sell. However, women were identified as being the main processors for wild meat markets and tourist/artisan markets. This could be attributed to various factors such as cultural traditions, skill sets, and economic opportunities that have historically

"a" Gender and drivers of wildlife trafficking: insights from South America

"b" Poaching

According to interviewees, poaching in the region is reportedly almost fully perpetrated by men, reiterating the considerable gender disparity observed in global poaching activities. They claimed that gender roles are often imposed due to exclusionary practices rather than being a matter of choice. Hunting is often regarded as a masculine practice typically passed down from fathers to sons, and many women do not learn the skill. Further, the idea that poaching brings a certain level of physical risk was brought up multiple times. A prevalent speculation, primarily among men, was that women do not hunt due to a fear of the forest. Several women agreed with the assertion; however, others attested that women were not scared of the forest, rather, they were scared of the dangers from people in forested areas. One interviewee said:

"Because women in the Amazon do not marry, they only live with the man, and it is a strong part of the culture that women have to do all the things that men need. Women do these things [participate in wildlife crimes], because they want to stay in a relationship. For the woman, the motive is not always to have more money. For the woman it’s, ‘I am going to do anything to be with you’. And men realize that, they know that. For men it is out of necessity and survival and also ambition. For example, transporting a jaguar or these protected plants pays you much better than working a month or even a year, both in the public and private sector.”

---

“Because women in the Amazon do not marry, they only live with the man, and it is a strong part of the culture that women have to do all the things that men need. Women do these things [participate in wildlife crimes], because they want to stay in a relationship. For the woman, the motive is not always to have more money. For the woman it’s, ‘I am going to do anything to be with you’. And men realize that, they know that. For men it is out of necessity and survival and also ambition. For example, transporting a jaguar or these protected plants pays you much better than working a month or even a year, both in the public and private sector.”

"c"Poaching

According to interviewees, poaching in the region is reportedly almost fully perpetrated by men, reiterating the considerable gender disparity observed in global poaching activities. They claimed that gender roles are often imposed due to exclusionary practices rather than being a matter of choice. Hunting is often regarded as a masculine practice typically passed down from fathers to sons, and many women do not learn the skill. Further, the idea that poaching brings a certain level of physical risk was brought up multiple times. A prevalent speculation, primarily among men, was that women do not hunt due to a fear of the forest. Several women agreed with the assertion; however, others attested that women were not scared of the forest, rather, they were scared of the dangers from people in forested areas. One interviewee said:

“No, women don’t go to the forest, but not because they are scared of the animals, it’s the men. The forest is dangerous because of people.”

"d" Transportation

Women were notably more engaged in the transport of illegally sourced wildlife. It was reported that women and children are used in transporting illicit wildlife on roads and rivers coming from the Amazon region because they are seen as less conspicuous. According to one interviewee:

“I’ve seen women and children on the rivers, taking and bringing [illegal wildlife]. They are starting to use children more, I think.”

This tactic leverages societal perceptions of gender and age, revealing a calculated driver behind the roles assigned within the illegal wildlife trade. Other regional studies have also shown women having pronounced involvement in transport of illegal wildlife in the Congo and Viet Nam."e,f

"e" Processing, preparation, storage

Processing and preparation of wildlife products was seen as a role mainly for women, but this was not consistent across all trade chains. For instance, medicinal products derived from wildlife (e.g. oils, salves, creams) were reported to be processed in the forest by men and brought into the markets already packaged and ready to sell. However, women were identified as being the main processors for wild meat markets and tourist/artisan markets. This could be attributed to various factors such as cultural traditions, skill sets, and economic opportunities that have historically
positioned women to excel in these roles more frequently than men. Further, it was found that women assume the primary caretaker roles in the live animal trade, responsible for looking after animals prior to sale or before the animals are moved on to other intermediaries. One of those interviewed said:

“For small mammals, [men] do not often take care of them—the women take care of [the animals]. I’ve seen more than once, women that have had a baby, a human baby, they also breastfeed the baby monkeys as well as other mammals before they sell them.”

Selling

The most dominant finding across all three surveyed areas was that women are the primary market sellers of wildlife products. Similarly, in local markets in Central Africa, women have reportedly been primary actors involved in the sale of wild meat and other wildlife products. This reflects a gendered division of labour that is characteristic of small-scale informal enterprises in many places; men’s labour is often frontloaded at the beginning of production chains, while women play roles as the vendors or traders.

Consumption

Although drivers of consumption are diverse and intricate, examples of gendered consumerism could be observed in the studied area. For instance, the practice of keeping wildlife as pets is prevalent, with demand coming from both men and women. However, it was widely perceived that women exhibited a greater interest in adopting wildlife as pets for companionship. One interviewee said:

“We are often the ones most responsible for having [illegal] wildlife in homes... they create more emotional bonds with the animals.”

This theme came up in many conversations and interviews, where women overall were said to be more interested in owning or caring for wildlife as pets because their social roles kept them tied to home and wildlife offered them companionship. It is unclear whether women themselves were enthusiastic about acquiring pets.

Lastly, the study revealed a pattern where international tourists sought wildlife souvenirs, driving the demand for illicit wildlife trade. Keepsakes crafted to attract tourists drive a market for products made from parts of the flagship species of the Amazon region (e.g. jaguar, otter, bear). Teeth, bones, feathers and skins are some of the most utilized wildlife specimens in souvenirs. Most of the artisans and sellers of these products are women, often from indigenous communities. The involvement of indigenous women places them at a complex intersection of tradition, survival, and the broader implications with their participation in illicit wildlife trade. The tourism demand has led to exploitative practices and the potential alteration of traditional cultural practices. According to one interviewee:

“There are a lot of indigenous people near here selling artisan [handicrafts] containing illegal wildlife, but this is the thing: that this is not a part of their culture. They are acting that way to attract more tourism. Because the communities further away—the real [indigenous nation omitted for anonymity] communities—they don’t do that. It just shows you how impactful tourism dollars are; it changes culture, changes what people would do.”

Preliminary insights suggest gender differences in the demand for these products. Women were found to be more likely consumers of wildlife products that are fashioned into jewellery and trinkets (e.g. purses and earrings made from jaguar pelts), a finding supported by studies in other geographies.

Drivers of demand

Context

At the end market there are many distinct wildlife use clusters with specific demand characteristics driving both legal and illegal trade flows. Wildlife is in demand for its use as food, as medicine, in fashion, for ornamental purposes, investment pieces and as pets, for example. Each of these demand clusters has its own trends and dynamics, and some operate in isolation from the others. For example, the factors that affect demand for python skins, such as fashion trends, are distinct from those that affect demand for python meat or demand for live pythons as pets. Preventing the illegal trade in pythons requires an understanding of these different sources of demand and why, in some cases, they favour illegal rather than legal sources of wildlife.

In the first edition of the *World Wildlife Crime Report*, the discussion centred on species in demand in several different types of markets. The table below lays out a modified version of these demand clusters, with adjustments based on more recent trends and market insights (Figure 4.3). The typology of market clusters is not exhaustive, and it would be difficult to come up with a comprehensive set of categories. Furthermore, it is important to recognize that wildlife trafficking flows for some species may supply more than one of these market segments, an example being rhinoceros horn used both as medicine and for carving into decorative items. Some additional demand clusters not included here are unique to a narrow range of species, such as the demand for primates for medical testing.35

The table also summarizes information on the nature of the use of the commodities traded in each demand cluster, because this provides some basic insights into forces that shape supply. For example, non-perishable products can be stockpiled, opening these products to speculative procurement binges. In contrast, perishable products such as meat or fish must be consumed within a short period of time after harvesting if kept fresh, and even after smoking or freezing viable storage times are limited. Products that are completely consumed, such as foodstuffs, may have a continuous source of demand, while end markets for non-perishable goods, such as specialized collectable items may involve one-off purchases. Additionally, the table includes a crude expression of the scale of demand for each cluster, distinguishing goods for which demand is for bulk quantities of consistent quality from those for which niche demand seeks novelty and exclusivity.

The dynamics of each of these demand clusters is discussed in turn below. In each case the analysis begins by considering factors that drive and shape demand for the cluster as a whole, whether legally or illegally supplied. Then for each cluster the specific features of demand linked specifically to illegal supply is elaborated. This approach is adopted because in all cases drivers related to illegal trade are grounded in factors shaping demand generally in the demand cluster.

Food

Data from FAO and other sources summarized in the 2022 Intergovernmental Science-Policy Platform on Biodiversity and Ecosystem Services (IPBES) thematic assessment on sustainable use of wild species indicated that at least 10,000 wildlife species are used for food, including those from fisheries, hunting of terrestrial animals and harvest of wild plants and fungi.36 Although much attention to use of wild foods has focused on tropical and subtropical areas,37 use of wild animals and plants for food is common globally. For example, estimates of the quantities of wild meat, mushrooms, and berries marketed annually in the European Union reach into the hundreds of millions of kilograms; it was estimated that 65 million European Union citizens were gathering and 100 million consuming wild food in the early 2010s.38

Demand factors range from the need for basic nutrition through to the preferential choice for speciality food items, such as sturgeon caviar. Since some species are valued for their associated health benefits, there can be some overlap with factors driving medicinal demand for wildlife. Species in demand are often locally accessible, but there are others for which long-distance supply chains have become established from rural to urban areas within source countries, internationally and between continents. Some wild species in demand are now supplied from captive production or farming.39 Preference for wild food may be a novel...

</table>

lifestyle choice, but often it is retained culturally as people move from rural to urban areas or migrate internationally. For people using wild species for basic nutrition a major factor in consumption choice is the availability and comparative price of alternative foods.

Concerns about overexploitation of wildlife species used for food and other risk factors has led to adoption of legal restrictions on hunting, harvest and trade in many countries and some species involved are subject to regulation of international trade under CITES. Populations of some species in demand may also be increasingly confined to protected areas where hunting and collection is not permitted. Both local and international harvest and trade regulations may allow for some conditional sourcing and trade, for example through seasonal restrictions or licensing. However, significant trade flows for some species continue illegally, knowingly or unknowingly in contravention of applicable law in many countries.

Research into specific consumption motivations for illegal wildlife used for food is typically geographically restricted or focused on particular species. As for the legal segment of this cluster, some purchasers seeking basic nutrition likely have limited alternative choices, while other consumers may be motivated by cultural tradition, taste preferences, price or niche interest. Some research has shown peer pressure to influence consumption choices, though generally it is likely to be an individual decision. In end markets, whether local or remote from sourcing areas, the legality of wildlife-derived foods may be difficult for consumers to discern and in some circumstances for speciality foods, demand may even be attracted by the illicit nature of the meal.

Medicines

Wild animal and plant species are widely traded for medicinal and associated health-related uses. The
global trade in wild plants involves as many as 30,000 species, mostly wild-collected and used for modern and traditional medicines, in health supplements, cosmetics and as food ingredients. The diversity of animal species used for modern and traditional medicinal purposes is less comprehensively documented. Although traditional medicinal use of products such as pangolin scales, rhinoceros horn, bear bile or tiger bone gain significant attention in commentary on wildlife trade issues, there are many other species used in this demand cluster. Less well-known examples include horseshoe crabs used for vaccine production, and medicinal leeches used for surgical and therapeutical purposes.

Traditional medicine systems continue to be used by large shares of the population in many parts of the world. A recent WHO overview noted that 170 countries reported traditional medicinal practices to be in current use by their population, including a wide range of medicinal systems, such as herbal medicine, traditional Chinese medicine, indigenous traditional medicine and ayurvedic medicine. One recent meta-study estimated an average traditional medicine use prevalence in 58 per cent of the total population in sub-Saharan Africa, although rates between studies varied substantially. A study in Viet Nam found a mean frequency of use of traditional medicine to be six times per year, with over 90 per cent of respondents reporting an improvement in health as a result.

Wildlife parts used for medicine may appear in end markets in unprocessed form, particularly as dried ingredients such as seahorses, deer antlers, vulture skulls or ginseng roots. They are sometimes purchased directly by consumers from retail outlets, but also commonly prescribed and dispensed by traditional medicinal practitioners at the point of sale. Other medicinal ingredients from wild animals and plants are processed into packaged medicinal products and it can be difficult for users or regulators to ascertain which species are included.

Complementary medicine use, including practices employing wildlife ingredients, is motivated by concern about health and includes treatment of illness, alleviation of symptoms and prevention of disease. A review of evidence on why complementary medicine is chosen indicates a range of motivations, from affordability to desire to avoid the side effects of modern pharmaceuticals. The distinction between medicines chosen individually by end users and those for which prescription decisions are made by medical professionals is important for design of any intervention aimed to influence decision-makers driving demand.

As in the case of wild meat, medicinal uses typically demand large quantities of wildlife ingredients and the sourcing and trade of many of the species is now subject to national regulation and for some, international trade control under CITES. Again, there remain conditional trade options for many wildlife products used in medicine, though some, such as rhinoceros horn and tiger bone, as explained elsewhere in this report, are subject to comprehensive trade prohibitions. Research into consumer motivations to continue use of prohibited wildlife ingredients for medicinal use indicates a diversity of attitudes on the balance between health concerns and associated environmental harms or illegality.

**Mass market pets and ornamental plants**

Some wild animals and plants are traded in large numbers to be kept and nurtured alive by hobbyists as pets or ornamental plants. The mass market trade in “exotic” pets has a long history, particularly the keeping of wild birds and aquarium fish, and more recently reptiles, amphibians and other species. This growing market has increasingly global reach. Wild-sourced supply is supplemented by commercial captive breeding and hobbyists may themselves become breeders, sometimes using the proceeds of sales to support their own further purchases.

The legal international trade in live wild animal pets is large and diverse. The proportion of this business subject to CITES trade controls involved 5 million birds, 41 million reptiles and 0.5 million amphibians during the period 2011–2020. Trade volumes for species not covered by CITES are difficult to estimate as many countries do not keep or publish relevant statistics. Patterns of supply and consumption are complicated and evolving over time in response to regulation and emerging demand trends. Similarly, the trade in ornamental wild plants for private keeping involves a wide range of species, some of which are subject to trade regulation. CITES legal trade data for 2011–2021 included movements of over 180 million snowdrops
and almost 5 million cyclamens, all reportedly wild-sourced.66

Unlike specialized collection demand described separately below, the pet and mainstream ornamental plant trade is characterized by bulk supply to satisfy demand for animals and plants that are reasonably easy to keep, with aesthetic or interesting features. Consumer research indicates that the exotic pet market demand cluster is not typically motivated by rarity or wild provenance and that captive bred animals and artificially propagated plants may be preferentially sought.67

Nevertheless, some of the species in demand for this cluster have become subject to national sourcing and trade restrictions and in some cases to international regulation under CITES. Where illegal trade occurs in connection with these market clusters, it typically involves species that were commonly traded legally before introduction of trade restrictions. High volume demand targeting popular parrot species in the pet trade persists despite national trade bans and CITES interventions. One species involved is the African grey parrot, for decades popular as a pet bird and now listed in CITES Appendix I. Despite the availability of a legal captive-bred supply, illegal trade in this and other parrot species competes to supply some markets through direct smuggling from source countries and falsification of captive breeding claims to launder wild-caught birds.68

It is typical in this demand cluster for legal supply to continue from commercial or hobbyist captive breeding of animals or artificial propagation of plants. The motivations for continued illegal sourcing and trade from wild sources are not well-researched but could include imbalance between the continuing demand being in excess of legal supply or that illegal supply has a price advantage.

Despite this demand cluster being typified by large volume trade in popular species, there are niche markets within the pet trade that target threatened and protected species. This is not a new phenomenon: the keeping of exotic animals has a long history among wealthy elites in various parts of the world.69 However a new dimension, particularly over the past decade, is the emergence of illegal markets for species such as otters, apes, cheetahs and other high value novel pets, inspired through exposure on social media channels, sometimes by high profile celebrities or influencers.70,71 Although the significance of the scale of demand is difficult to judge, it often focuses on juvenile animals, the acquisition of which may have wider collateral impact on wild populations.72,73

### Specialist market for live animals and plants

Some pet and ornamental plant owners turned hobbyist breeders may transition to the world of specialist collectors, people who dedicate enormous amounts of time and money to curating collections of objects for their personal enjoyment and for sharing with other admirers. The desire to create these collections is both ancient and commonplace. The collection instinct has even been tied to specific areas of the human brain.74 In the modern world, there is a community aspect to collecting, with those fascinated by certain objects forming clubs or societies, building expertise, comparing their collections with others, trading objects, and vying for status among their peers. The internet has brought collectors of rare objects closer together, reinforcing their behaviour and providing an international market to those who can source popular collectables.75

Specialist collectors of wildlife specimens—such as rare birds, reptiles (Box 4.3), or orchids—are potentially driven by a desire for a complete and balanced collection. Rare specimens are particularly prized.76 Since the natural world has been incompletely catalogued, the discovery of new species provides perpetual novelty to wildlife collectors. Once acquired, the challenges of keeping lesser-known species and being among the first to breed or propagate a species in captivity are additional motivations. The compulsion to acquire can become so great that the legality of the specimen may become a secondary consideration. Insofar as illegality creates scarcity, it may even add to the attraction.

Demand motivations for specialist collectors of live wildlife specimens are very different from others who keep exotic pets or ornamental plants. Research has shown exotic pet owners prefer species that are captive-bred, common in the wild, and abundant in the market. Collectors, in contrast, prefer almost exactly the opposite, wild species that no one else has.77 As described in the orchid case study in chapter
6 of this report, some specialist collectors may see themselves as unofficial conservators, rescuing species from the wild before habitat loss leads to their extinction.

**Exclusive market in goods for adornment, display and demonstration of status**

A wide range of wildlife commodities fall within this demand cluster, including elephant ivory, tiger skins and precious woods. Some are valued in unprocessed form, while the value of others may be enhanced through manufacture into items such as ivory carvings or rosewood furniture.

Although legal trade remains a source of supply for some components of this demand cluster, such as the use of reptile skins for manufacture of fashion goods, for others there is limited or no legal supply. As documented in previous editions of the *World Wildlife Crime Report* some of these goods, such as elephant ivory, have long histories of overexploitation and many are subject to strict trade regulation at national level and under CITES.

Demand for goods in this demand cluster may have some attributes in common with niche components of the food and medicine clusters, such as sturgeon caviar consumption or use of rhinoceros horn as a tonic cure for hangovers. Consumers may be motivated as much by the opportunity to follow cultural traditions or project status and wealth as they are by the intrinsic properties of the goods they desire. For some goods, such as rosewood or reptile skins, manufacturers and retailers may have strong influence on sourcing choices, while for others such decisions lie principally with individual consumers.

When legal supply to markets in this market cluster is restricted or unavailable, there can be strong incentives for illegal trade, with the combination of restricted supply and wealth-driven demand potentially leading to the situation seen with other “luxury” goods where high prices themselves become an added motivation for further purchasing.

At least one researcher has argued that rosewood, used for the manufacture of high status furniture, has become the object of speculation, with buyers accumulating stocks in anticipation of price increases. Previous editions of the *World Wildlife Crime Report* made a similar argument about elephant ivory market incentives in the 2010s. Speculation could also explain rapid rises in detected illegal trade in a wildlife product but no indications of a corresponding increase in end markets sales, as with pangolin scales, although no concrete evidence has been produced so far.

Considering other markets, alternative investments, such as antiques, artworks and rare books, are valued as potential means to hedge against inflation, currency devaluation and other factors when local mainstream investments are deemed unreliable. The attraction of these investments increases when their purchase becomes a status symbol, a marker of cultural sophistication. For example, fine art has become an attractive investment vehicle in a number of developing economies.

Once a wildlife commodity has achieved the qualities of a status symbol, it may be displayed as home decoration or worn as jewellery. This same quality makes them appropriate for gifting, a social obligation that may border on corruption. Such gifting can be difficult to distinguish from bribery in some contexts.

**Corruption and wildlife crime**

Public and private sector actors as well as individuals may be lured into corrupt behaviour to facilitate wildlife crime as they can obtain high profits at a low risk of being caught. Factors enabling corruption to flourish in the wildlife trade include, among others, the absence of effective sanctions, a lack of transparency in the public administration and other agencies, unclear accountability structures, and a lack of public disclosure of key documents. Criminals thrive on the existence of corruption as it enables them to commit, conceal and avoid conviction for their crimes. Corruption may take various forms and may evolve over time. The United Nations Convention against Corruption (UNCAC), the only global legally binding international instrument against corruption, does not provide a definition of corruption but instead identifies a series of corrupt acts that should be criminalized. Most of the corrupt acts listed in
There is a large international market for reptiles as pets as well as a community of hobbyists who breed reptiles to supply this market. Researchers have found that 75 per cent of this trade is in species that are not covered by CITES and approximately half of all traded reptiles are captured from the wild.\(^a\) As with orchids, there is a segment of this community that collects rare and protected species and sourcing and trade in many of those not subject to CITES trade regulation are nonetheless subject to national restrictions. These collectors compete to acquire newly described species as well as severely threatened and protected species.\(^b\)

According to a series of 20 interviews with traders and experts conducted for the *World Wildlife Crime Report 2020*,\(^c\) many collectors start out when children after keeping one of the “gateway species” (e.g. bearded dragons, crested geckos, leopard geckos and ball pythons) as pets. Through the internet, they are exposed to owners of rarer species and learn how easy these species are to acquire. Like orchids, many reptile species are amenable to being transported by post, and specialized shipping companies have emerged to facilitate the trade. Soon they too are online showing off their acquisitions to gain status among fellow collectors.

With reptiles, even general demand can pose an extinction risk. This is because, unlike orchids, many reptile species are relatively difficult to breed in captivity, sustaining the demand for wild-caught specimens.\(^d\) As national or international trade restrictions are introduced to address overcollection for this trade, persistent market demand drives illegal trade and also creates demand for similar species not yet subject to regulation, which in turn may be negatively affected.

According to the interviewees, social media communications were driving demand and one good photo of a novel species can prompt exponential sharing and market interest. Global social media platforms and specialized trading forums are key to the market. Where direct sales are not allowed, prices are often listed in the comments. Those hesitant to do business online can buy protected species under the counter at reptile shows.

New collectors may initially buy their reptiles through one of the many brokers online, but they soon learn that through the internet they can commission collectors to find any desired specimen, irrespective of legality. Customs clearance specialists are hired in the source countries to ensure the order arrives. Hobbyists often import surplus animals and use the proceeds from onward sales to fund their own purchases. In a similar manner to user-dealers with illicit drugs, hobbyist breeders are a key source of supply in both the licit and illicit side of the reptile market.

Like collector demand for ornamental orchids explored in the case study in chapter 6 of this report, published research on the exotic pet trade indicates that novelty and scarcity are among the key factors that attract specialist demand and higher values. Species that are only found in a limited geographic range, particularly island endemic species, are inherently scarce and so in demand from traders. Additionally, endemism allows for collectors to know exactly where to find a species. As trade diminishes supplies, the prices increase.\(^e\) Such patterns have been observed for several species groups in demand for the pet trade, including chameleons, iguanas and freshwater turtles.\(^f\) It may also incentivize greater effort to establish captive-bred supply, but this can take some time to be established at significant levels.

---

\(^e\) Marshall, Strine, and Hughes, ‘Thousands of Reptile Species Threatened by Under-Regulated Global Trade’.

Between November 2022 and April 2023, UNODC undertook interviews with selected experts involved in law enforcement, criminal justice or related research or capacity building in government and non-governmental organizations. Among 17 respondents interviewed, only six were able to speak about specific examples of which they had first-hand knowledge. The survey was organized to establish a baseline understanding of the nature of corrupt relationships that facilitate the illegal import/export of wildlife through points of entry and to identify research gaps, opportunities, and directions for future work.

The types of corruption incidents (e.g. through bribery, trading in influence, abuse of functions) that were discussed by respondents when describing specific cases involved the following:

- Bribed to turn a blind eye and not inspect shipments at checkpoints.
- Provided access to information (e.g. patrol schedules for coastguard).
- Paid bribe to avoid arrest following detection by authorities.
- Abused functions by providing falsified documents (e.g. CITES permits).
- Abused functions by reselling confiscated wildlife.
- Bribed a public official to provide direct assistance physically to move the product through checkpoints.

Government officials involved in the schemes ranged from entry-level to senior management and higher-level government officials were suspected to be involved in some instances. Functions included: coast guards, customs, police and environmental agencies. In some cases, a government official was directly involved or leading the transnational shipment of wildlife. In terms of rewards, the government officials in all the described incidents received monetary gains for their participation in corrupt activities.

Establishment of corrupt relationships:
- Through collaboration with family or friends.
- An employment position had provided the opportunity to meet and connect with people involved in trade and access resources to facilitate illegal trade.
- Social networks had exposed officials to potential corruption by traffickers.
- Some corruption was reactive, a response to being detected.

Maintenance of corrupt relationships:
- Relationships generally continue because they are mutually beneficial.
- Some get locked into relationships through coercion (e.g. threats of violence).
- Some relationships can last for long periods of time (years).
- Some participants hide schemes through concealment methods, but some do not hide them because there is nothing to stop them continuing (systemic issues).

Breakdown of relationships:
- A conflict between the parties had emerged, perhaps related to a loss of trust although details were not clear.
- Some relationships were no longer beneficial although this raises questions about how suitable alternatives are found or if services are no longer needed (e.g. no one checks at the border regardless of whether bribes were on offer).
- There was little knowledge of what happens to corrupt relationships when they are detected—whether this causes the corruption to stop or be displaced to other people.
the Convention are employed by public officials who facilitate wildlife crime perpetrators who may offer bribes to officials for information on the movement of wildlife or patrols, to obtain licences or permits, to allow illegal specimens to pass through controls and borders, or to ensure that illegal shipments are not inspected or seized, as well as money-laundering to conceal the proceeds of crime. 84,85 Corruption is an enabling element of wildlife crime at all stages of the trade chain. In source countries, first line wildlife defenders are an obvious target for traffickers as they are often poorly paid for what can be dangerous work. One study found that in just one section in the south of Kruger National Park in South Africa, 14 of its 20 rangers have been linked to poaching networks, many recruited with a combination of promises and threats. 86 In some cases, the rangers may become poachers or traffickers themselves. A ranger in Zimbabwe was recently arrested alongside a police officer and a retired police officer in a sting in which they offered to sell almost 30 kg of ivory to undercover officers. 87 When active rangers cannot be corrupted, former ones may be the next option as they have first-hand knowledge of the enforcement mechanisms that must be circumvented. Operation Blood Orange in South Africa implicated two former park rangers who, “Provided tactical information to rhino poaching syndicates in exchange for substantial sums of money.” 88 An overview of how corruption impacts wildlife ranger work highlighted weak governance systems as a critical vulnerability. 89

In some countries the revenues related to wildlife trafficking are apparently attractive enough to extend corruption to senior levels of government. For example, in 2023 the Government of the United States barred entry by three senior government officials responsible for wildlife trade regulation in the Democratic Republic of the Congo, for allegedly, “Trafficking chimpanzees, gorillas, okapi, and other protected wildlife ... using falsified permits, in return for bribes.” 90 This is not the first time this particular management authority has been implicated: a 2018 international investigation into an attempt to export African manatees resulted in the arrest of a staff member from the CITES Management Authority in the Democratic Republic of the Congo. 91 Reviews of evidence on corruption links to wildlife trafficking have highlighted arrests and conviction of senior government officials in a range of countries in Africa, Asia and Latin America. 92,93,94

Another point of vulnerability is government stockpiles. In 2018, a customs official in Viet Nam was reportedly sentenced to 16 years in prison for stealing ivory and rhino horn from government stockpiles. 95 A similar case emerged in 2023 in Malaysia involving pangolin scales. 96 A series of ivory seizures have been connected through inventory markings and isotope analysis to Burundi stockpiles, and a similar situation pertains to the rosewood stockpiles of Madagascar. 97 Other forms of corrupt acts could well be applicable to these cases, such as diversion of property, embezzlement, trading in influence and abuse of functions, all of which are listed in UNCAC.

The role of corruption as a facilitator of wildlife crime is receiving increased attention and research effort in recent years. This issue was specifically flagged as a growing concern and focus for action in a 2016 CITES resolution, 99 and the urgent necessity to address environmental crime and corruption was the subject of a 2019 resolution of the UNCAC Conference of the States Parties. 100 A range of analyses have been published on the role of corruption in enabling illegal wildlife trade flows generally or with respect to specific commodities, including rhinoceros horn and sturgeon caviar. 101,102,103 Available evidence also reveals that women and men experience, participate in, profit from and lose from corruption differently. 104

To gain some deeper understanding of the underlying mechanisms of corruption linked to wildlife crime, UNODC organized a review of case examples for which corrupt acts were directly addressed by prosecution rather than referred to indirectly in cases typically tried under wildlife legislation. However, limited source data was found to be available. Such information could be of high value for the identification of possible points of intervention and to gain an understanding of why prosecution under laws directly addressing corruption is apparently uncommon, despite potentially higher penalties. To try and address this evidence gap, a consultation was carried out by UNODC in 2022–2023 to seek insights from experts with case-level experience about how corrupt relationships that facilitate the illegal wildlife trade are established, structured and maintained (Box 4.4). These findings are summarized in Figure 4.4.
Insights from the expert interviews and case studies for the current report illustrate that wildlife crime-related corruption has much in common with corruption affecting other legal and illegal economic sectors. Participants bribed to facilitate illegal wildlife trade at transport checkpoints and borders provide the same services in relation to other forms of contraband, while the road checkpoint corruption described in the rosewood case study in chapter 6 of this report is clearly a liability for passage of legal goods too. For wildlife crime, specific vulnerabilities are likely for specialized public sector roles such as harvest and trade permit issuance, animal health and phytosanitary inspection, and control of specialized retail outlets. However, the evidence base for specific points of vulnerability and on the effectiveness of risk mitigation responses for such roles remains weak.
Endnotes

2 Other harms do of course occur along the trade chain after sourcing, as elaborated in chapter 2 of this report, including negative environmental, social, economic and governance impacts of wildlife trafficking and associated crime.

3 Such interdictions may of course have other benefits in reducing harms along the trade chain, including prevention of the use of proceeds from crime.

Chapter 5

What works?
What works to decrease wildlife crime?

Policy makers, regulatory and enforcement agencies, and funding institutions have good reason to seek insights into which interventions are effective in decreasing wildlife crime and in what contexts success has been achieved. Such knowledge can inform decisions about which interventions to fund or implement and which policies to pursue.¹

A critical question to consider in assessing the impact of interventions aimed to decrease wildlife crime is what constitutes success? In basic terms, levels of criminal activity are expected to decline and flows of illegal trade to decrease, leading to a reduction in the severity of the various types of harm discussed in chapter 3 of this report. As harms reduce, positive benefits may result, such as recovery of wildlife populations or restoration of lost livelihoods.

It is not easy to measure the impact of crime reduction interventions although for some, immediate results may be obvious, such as increased arrests or seizures arising from an increase in patrolling or inspections. Others, such as the outcome of interventions aimed to deter or disrupt trafficking or reduce opportunities for crime, are more difficult to assess. In such cases a successful outcome is that a potential criminal act does not take place.

Furthermore, it is also difficult to discern which results arise from a specific intervention and which relate to other causes of change in the levels of crime and related harms that might have occurred regardless. There is also the question of how to assess and view displacement of crime. One intervention may have a positive impact in one location or on one commodity but may or may not push the crime to other locations or other commodities.
Globally, most interventions to reduce wildlife crime are likely managed and resourced from within individual government budgets. This includes financing ranger, police, customs, and criminal justice functions. There is limited available data to quantify such investments, in part because they are typically embedded within budget allocations, such as an annual allocation for policing or customs controls. It is also important to recognize that there is likely considerable variability at a national level in terms of the adequacy of these allocations.

Funding to address wildlife crime is also provided by multi-lateral, national and private donor institutions. While it is not possible to assess how the level of such international donor funding compares to the financial resources spent by national governments to tackle illegal wildlife trade, useful information is available on where and how it is allocated. A World Bank survey of multilateral and bilateral donor agencies, foundations, United Nations programmes and international non-governmental organizations found that over $1.3 billion had been committed between January 2010 and June 2016 to combat illegal wildlife trade in Africa and Asia, approximately $190 million per year. Donor funding was allocated to projects in 60 different countries and to various regional/multi-country and global projects. In total, 63 per cent of the funds were committed to Africa ($833 million), 29 per cent to Asia ($381 million), 6 per cent to global programmes and initiatives ($81 million), and 2 per cent to projects covering both Africa and Asia ($35 million). The top five recipient countries accounting for $328 million were: United Republic of Tanzania (8 per cent), Democratic Republic of the Congo (5 per cent), Mozambique (5 per cent), Gabon (3 per cent), and Bangladesh (3 per cent).

The purpose of funding allocations was broken down into various categories (Table 5.1).

This significant volume of funding begs the question as to whether the interventions funded by these donors were effective. Notably only 6 per cent of the funding was allocated to research and assessment. This limited investment may in part explain why the evidence base for the efficacy of interventions to counter wildlife crime is so limited.

The evidence-base for the identification of what works and what does not work to prevent wildlife crime is in the early stages of development. Existing prevention efforts draw primarily on the knowledge and expertise of individual practitioners, qualitative learning, and inference from logic models. Formal evaluations of wildlife crime prevention are rare, particularly those with strong evaluation designs.2

Intervention planning for some other crime sectors benefits from more sophisticated evaluations of interventions and a strong body of professional experience and research provides helpful insights into what works for crime prevention. Some of the insights from other sectors can help widen the scope of approaches used in responding to wildlife crimes.

This chapter begins by classifying different types of interventions to counter wildlife crime. It then probes evidence about which of these interventions work best to reduce wildlife trafficking levels and related harms, based on available literature and some illustrative examples. The chapter then takes stock of what can be learned from the evidence of what works to address other crime types and refers to some existing sources of guidance on how such approaches might be applied in the wildlife crime sector. Finally, there is a discussion of future needs for building and using evidence to evaluate outcomes and impacts of crime prevention interventions properly.

**A taxonomy of interventions to counter wildlife crime**

Several types of intervention are currently employed to reduce wildlife crime and illegal wildlife trade. The approach in the following analysis is focused primarily on wildlife crime interventions intended to engage directly with the people involved or potentially involved in the criminal supply chain. They are separated into three generalized trade stages, at source, in trade and at consumption. Criminal justice interventions, treated as a fourth distinct category, are applied at all of these trade stages (Figure 5.1).

These wildlife crime interventions are distinguished from other types of action that are aimed to shape or shift the enabling environment in which wildlife crime takes place. As illustrative examples, a change in trade rules through legislation or a new mechanism for inter-agency cooperation may be critically important in shaping the environment for reducing illegal wildlife trade. However, such initiatives will only have impact when implemented through direct wildlife crime interventions, whether that be simply through deterrence triggered by publicity about the new initiative or through active enforcement action.

**What evidence is there about which interventions to counter wildlife crime work best?**

There are remarkably few published systematic assessments of the effectiveness of wildlife crime interventions. When such assessments are carried out, their value as a basis for evaluation depends largely on whether they can draw a clear comparison between the situation before and after remedial interventions were made.

One group of researchers used a systematic mapping approach to collate the existing body of literature addressing the effectiveness of interventions to counter wildlife crime, including those that directly protect wildlife from illegal harvest, detect and sanction rulebreakers, and interdict and control illegal wildlife commodities.3 The “effectiveness” of interventions was viewed in terms of whether they could be linked to biological or threat reduction outcomes.4 The focus was plant and animal species targeted by the international grant programmes and law enforcement activities of the United States Fish and Wildlife Service (USFWS), specifically those directly threatened by exploitation and native to Africa, Asia and Latin America.5

Preliminary results of this research have been provided to UNODC for the current report in advance of publication as follows:

» 530 studies from 477 articles met the inclusion criteria and were subsequently included in the systematic map (Figure 5.2).

» The most common species groups for which relevant studies were identified were African and Asian elephants (16 per cent of studies), followed by felids (14 per cent), and turtles and tortoises (11 per cent).
FIG. 5.1 A taxonomy of interventions aimed to counter wildlife crime and actions aimed to shape the enabling environment

Wildlife Crime Operational Interventions

**At source**
- Reducing and mitigating human-wildlife conflict
- Supporting legal livelihood options
- Reducing incidental take
- Guarding by law enforcement or private and community rangers
- Reducing availability of and removing snares and weapons
- Area access controls
- Local surveillance and intelligence gathering

**In trade**
- Warning to traders and travellers
- Inspection of commercial breeding operations
- Stockpile and inventory control
- Inspection and control at border and market hubs
- Identifying falsified documentation
- Pinpointing corruption
- Building safeguards in supporting businesses to reduce facilitation
- Intelligence gathering on crime networks

**End market**
- Possession controls and inspections
- Consumer behaviour change communications
- Enabling access to legal, traceable alternative supplies
- Promoting substitutes

**Delivering justice**
- Confiscation and other immediate sanctions
- Arrest
- Prosecution
- Conviction and penalties (financial and imprisonment)
- Asset recovery
- Rehabilitation of offenders

**Shaping the Enabling Environment**
- Strengthening treaties and national laws
- Catalysing international and inter-agency cooperation
- Building capacity of implementing institutions and personnel
- Strengthening the wider criminal justice system
- Building general awareness of harms and impacts
- Researching, evaluating and guiding adaptation of wildlife crime responses

Source: UNODC
» Approximately 90 per cent of the evidence base included an evaluation of interventions to counter wildlife crime employing only post-intervention data and lacked any before/baseline intervention data or spatial comparator.

» Only 11 per cent of the evidence base used direct biological measures (e.g. increased wildlife population numbers) to evaluate intervention effectiveness; instead, most often, threat reduction (e.g. fewer poaching incidents) or intermediate outcomes (e.g. increase in offender arrests) were used as indicators of a potential or perceived change in population/species outcomes.

» Many knowledge gaps still exist in examining interventions to address wildlife crime for (1) Latin America, (2) all relevant plants (e.g. rosewoods, mahoganies, cycads, succulents, aloe), (3) reptiles and birds, especially related to actions aiming to prevent the loss of target wildlife species from their habitat by illegal harvesters (i.e. wildlife population-centric actions), and (4) non-patrol-based interventions to counter wildlife crime.

» Among the different intervention types and impacts covered by the systematic mapping, “the effectiveness of patrol regimes on population abundance” was identified as a candidate for further synthesis, based on the presence of sufficient pre- and post-intervention evidence.

» Initial findings of this further analysis indicate that overall, for areas implementing a patrol regime (alongside other interventions) there was an increase, on average, in wildlife abundance of African, Asian, and Latin American wildlife directly threatened by exploitation compared to a time period(s) or location(s) where no patrols (or some baseline level of patrols) were conducted. However, causality is difficult to confirm.

» Detailed results of the study can be found in the published paper and a deeper analysis of variability within the patrolling subset will be published in due course.

An earlier systematic review focused specifically on interventions to prevent crime involving terrestrial species. This review was based on a full text assessment of over a hundred published articles on wildlife crime prevention and sought quantitative evidence of effectiveness in delivering positive outcomes in reducing crime and poaching impacts on species populations. The study discovered that only five of these studies met the inclusion criteria for further analysis. Some were excluded because they did not focus on direct crime prevention interventions, others because they lacked outcome evidence. The five retained studies took place in four different countries, two in Asia and two in Africa (two different studies in one African country). Studies focused on the impact of anti-poaching patrols indicated that they were effective to a larger or lesser extent in decreasing the prevalence of poaching. Factors highlighted as influencing the efficacy of anti-poaching patrols were: the habitat’s accessibility; rangers’ level of experience and numbers; the time spent patrolling; the longevity of patrols; the type of patrol conducted; the type of target and its mobility; and the bonus/incentives provided to patrollers. The studies also shed light on various supporting conditions for patrol efficiency that those designing anti-poaching patrols might consider. However, the results are from a low number of studies focused on rhinoceros, elephants, and tigers.

A recent review of 115 case studies of community-based interventions to counter illegal wildlife trade featured on the People Not Poaching platform aimed to understand their effectiveness and how this was measured. It noted that not all studies provided sufficient evidence to understand how they had determined their intervention was effective at reducing poaching. When they did do so, frequently used indicators were process rather than outcome based, like the number of poaching incidents detected or the number of seizures made, or even the number of individuals involved in education or awareness raising activities. This made it difficult to discern if a reduction in poaching had occurred. This study also noted that behavioural change on the part of poachers was primarily measured by observation rather than quantitatively. In conclusion, it was suggested that future evaluations of community-based approaches to wildlife crime prevention should use stronger social science methods to assess behavioural change in addition to using direct measures of intervention success such as ecological indicators (population numbers, changes in reproductive rates).
FIG. 5.2 Heatmap of wildlife crime studies by intervention and measured outcome type

Number of (all) cases

Source: Rytwinski et al., 2024
at the other end of the trade chain, a recent meta-analysis of communication campaigns and other initiatives potentially impacting illegal wildlife consumption in selected countries in Asia assessed evidence of reductions in indicators of consumer demand. Post-campaign evaluation through market surveys indicated an average 50 per cent drop from 2018–2020 in consumers’ intent to buy wildlife products and a 30 per cent decrease in perceived social acceptability of buying and using wildlife products. Research also showed significant reductions in demand related indicators, including attitudes/beliefs driving consumption, social acceptability, and intention to purchase. However, these findings are not definitive in terms of reducing actual demand. Demonstrating links between attitudinal changes and reductions in actual purchasing behaviour is difficult and requires triangulation with other measures of market trends.

Overall, the challenge of finding evidence of what works remains. Many evaluations are designed only to measure process outputs rather than outcomes and many are carried out within short-term projects before it is realistic for impact to be noticed. Even the more ambitiously structured evaluations can fail to discern clear patterns. Indeed, it is technically very challenging to evaluate quantitatively how interventions, often with multiple elements, impact complex social-ecological systems. Moreover, the scope of interventions that are evaluated is geographically and thematically biased. For example, a review of the Conservation Evidence platform database for primates showed that: 1) fewer than 1 per cent of studies evaluated conservation effectiveness, and 2) those studies that included an evaluation were biased geographically on certain types of interventions and on specific taxa of primates. Evaluations undertaken by institutions typically focus on understanding the impact of their priority interventions. A 2015 USAID review of the metrics used to assess illegal wildlife trade interventions focused mainly on two strategic approaches: building capacity for effective enforcement and prosecution; and improving monitoring and response to the status and trends of wildlife and wildlife crime together. These two strategic, but non-operational intervention types, accounted for 70 per cent of the metrics reported on.

Learning from success

Despite the paucity of impact-level evidence, it is nevertheless informative to consider cases in which success at an outcome level has been demonstrated. Actions taken to address wildlife crime and indicators used to measure outcomes are summarized in Box 5.2 for four examples of successful wildlife crime interventions compiled for a 2020 guide on problem-oriented wildlife protection. These successes in reducing wildlife crime indicate that, despite the size and scope of the global illicit wildlife trade, there are grounds for cautious optimism. The case studies summarize the preventive responses and the indicators for interventions with manta rays, amur falcons, leopards, and illegal fishing. They are described here using the problem-solving cycle for crime reduction known as SARA (Scanning, Analysis, Response, and Assessment).

Common characteristics of the successful case studies include the diverse information gathered, the focus on a specific rather than generalized problem, and the locally appropriate responses introduced. A set of responses, rather than a single response, was common, and crime prevention research suggests that a set of measures is more effective because they reinforce each other to positive effect. The interventions in the case studies worked via numerous mechanisms. Some initiatives blocked crime opportunities, including promoting the accountability of fishing vessel movements, and removing nets used for falcon trapping. Such measures reduce access to targets, facilitate compliance with the law, and make it much harder for offenders to act. Other responses reduced the reward to poachers, including the distribution of subsidized leopard skins to reduce the market for illegal products and the promotion of tourism that encouraged local conservation with a set of guidance rules, increased formal surveillance, and alerted the conscience of local poachers. Where traditional law enforcement techniques, such as patrols and arrests, were used, it was complementary to other responses.
Example 1: Foiling falcon trapping in India

The Amur falcon is the longest-distance migrant raptor in the world and passes through Nagaland, India, where it is nationally protected, as part of its 22,000 km annual migration from North-East Asia to Southern Africa. Through Scanning of the case, it was clear that the problem was large-scale trapping of migrating Amur falcons at Doyang Reservoir in Nagaland for cheap meat. Analysis showed that falcons were killed during a 10-day period when congregating for migration. Around 70 hunter groups in three villages used fishing nets to catch the birds. Research indicated that trapping did not have a cultural motivation and that trapper behaviour might be strongly influenced by village council and male local religious leaders. In Response, the Nagaland Fisheries Department seized nets and posted reservoir guards, local leaders discouraged falcon consumption, hunters were supported to transition into tourist guides and falcon protection teams, eco-clubs were established, and falcon protection encouraged. Assessment found that falcon trapping declined from at least 120,000 birds in 2012 to zero in 2013 with minimal evidence of illegal harvest during subsequent surveys through to 2019.²³

Example 2: Interrupting illegal fishing in Australia

Scanning of the problem identified illegal commercial fishing in unapproved areas or at unapproved times. Analysis showed that fishers bypassed regulations by failing to install a vessel monitoring system (VMS) on board and/or have it always operating. In Response, a team was formed that cross-checked logbooks against VMS data within three days of landing, along with a zero-tolerance policy whereby patrols forced vessels without VMS to return to port. Assessment found VMS compliance rates increased from 87.5 to 97.9 per cent during the study period in the mid-2010s.⁴

Example 3: Protecting manta rays in Indonesia

Scanning of evidence determined that the problem was illegal hunting of manta rays in Eastern Indonesia, where these species have been protected since 2014. Hunting was motivated by demand for manta ray gills in traditional medicine markets elsewhere in Asia. Analysis determined that one village was the location of the illegal hunting and market, with a group of repeat offenders who targeted concentrations of manta rays at certain times. The Response was patrols focused on the problem times and locations. High-level traders were prosecuted, supported by training of the judiciary. Livelihood interventions were focused on hunters, processors, and the community. Assessment found manta ray hunting in the intervention area declined 85 per cent in 2017 compared to the 2013 baseline.⁶

Example 4: Lessening leopard poaching in South Africa

Scanning of the situation identified the problem as illegal, unlicensed leopard hunting for fur capes used in local traditional religious ceremonies. Analysis estimated thousands of leopard skins in use locally by one religious community within South Africa. Capes were costly and lasted seven years, but some community members used artificial capes. There was low awareness of leopards’ threatened status. The Response was the manufacture and distribution from 2013 onwards of durable synthetic leopard skins, initially free before transition to a sustainable business model, combined with education to reduce the desirability of wild leopard skins. Assessment showed the proportion of real leopard skins in use by the community likely dropped to 50 per cent by 2018.⁷

It can be argued that the decline of the ivory market described in the case study in chapter 6 of this report is also an illustration of how multifaceted interventions can bring success. These interventions include both demand and supply reduction strategies: introduction of stricter domestic market restrictions in China, Thailand and other countries in the late 2010s represented a major shift in the enabling environment. Operational interventions included market inspection and enforcement of new domestic trade restrictions, large-scale communication to both retailers and potential customers about risks of non-compliance, and an increase in international collaboration to identify and close important smuggling routes and networks. In combination, these measures appear likely to have contributed significantly to declining illegal ivory trade flows inferred by the triangulation of different indicators: poaching levels, seizures and market prices.

**What can be learned from the evidence of what works to address other crime types?**

There are gaps in the evidence of what works to reduce wildlife trafficking across all intervention types, from livelihood-related actions at source through to demand reduction in end markets. Based on the review in the previous section of this chapter, the shortage of evidence appears to be particularly acute for interventions aimed to disrupt criminal activity through law enforcement and other criminal justice actions. It therefore makes sense to take stock of the knowledge accumulated by criminologists and enforcement strategists who have evaluated interventions aimed to address other crime sectors. Some crime types that, for decades, appeared likely to continue to increase have been contained, and others significantly reduced. Car crime, burglary, and violence that once characterized high-income countries, have generally been declining for decades. This reflects the blocking of crime opportunities, particularly through security improvements to vehicles, households, businesses, and in many sectors of public and private life.

The following examples by no means represent a comprehensive review of research on action against other crime types, rather they illustrate the types of lessons that might be taken into account in shaping effective interventions to counter wildlife crime.

**Targeting enforcement effort**

Crime requires the convergence in time and space of a likely offender who is disposed to committing crime, a suitable target that is attractive to an offender, and the absence of a capable guardian to prevent the crime. These circumstances only come together at certain points and in certain places in a predictable pattern. However, some basic patterns hold true across crime types, providing insights about the circumstances when risk and the need for prevention are greatest. Examples include the concentration of crime in geographic hotspots, along certain routes, and on specific types of products. Identifying these patterns in crime can help target resources more effectively.

For wildlife crime, application might include focusing patrols on known access routes into national parks and enforcement at critical transport hubs. Caution is needed to avoid confirmation bias, so collation of comprehensive data for analysis of patterns and trends is of great importance. Gaining deeper understanding of participant motivations can also help with the forecasting of places and species likely to be targeted in future by wildlife trafficking.

**Understanding and predicting criminal behaviour**

Crime scientists have also shown that criminal behaviour can be predicted and manipulated. Offenders often make rational choices, but that rationality is bounded by their understanding of their environment, which is never perfect. They act in a certain way because of their own disposition and because of the cues and reinforcements that their environment provides. A car thief, for example, will choose to target a car that is easy to resell in a parking lot with fewer lights and no visible cameras at a time when they know few people will be parking or retrieving their cars. There is a logic why offenders choose to commit a crime and when and how they do so. Generally, offenders decide to commit a crime by weighing up its risks and benefits at a particular time and place, but they tend to focus on immediate, not long-term, risks and benefits. Understanding how these choices are made is key to designing effective crime prevention interventions.
For wildlife trafficking, as for other crime sectors, there is great potential to learn more about behavioural motivations from qualitative research, such as offender interviews, and to employ such insights to design and target interventions better.

**Designing for deterrence**

Understanding offenders’ decision making is also critical to using deterrence appropriately. The assumption is that punishments like prison will deter specific offenders because the experience of punishment will dissuade them from future crime.\(^2^8\) Meanwhile, others around the offender who see or hear of the punishment will be discouraged from criminal behaviour.\(^2^9\) However, the reality of deterrence is far more complicated. The general tenet of classical theories of deterrence is that punishment must be certain, severe, and swift to deter.\(^3^0\) However, deterrence hinges on the public perception of this and people are poor at accurately predicting arrest certainty or sanction severity.\(^3^1\) Overall reviews of deterrence conclude that perceptions of the severity of punishment show weak to no impact on crime levels, but the perception of certainty of punishment does.\(^3^2\) This is because people are remarkably good at assuming “getting caught could never happen to me, it only happens to the unlucky ones.”\(^3^3\) To design effective interventions, it is important to understand how first-time and repeat offenders perceive risk in their environment when making decisions. The goal is to increase the perception of risk through specific cues that counter crime interventions can place in the environment to deter offenders. An effective approach based on this insight, labelled “focused deterrence”, targets high-volume offenders with a combination of increasing perceptions of punishment certainty, while at the same time offering support through provision of social services.\(^3^4\)

Numerous examples in this report indicate that more strategic approaches to deterrence could enhance wildlife crime reduction interventions. Research in source countries indicates that participants in crime may underestimate risks. Perhaps of even greater concern, higher-level traffickers may perceive impunity and may count on the inefficiency of the criminal justice system. Some high-profile cases that dig deeper into criminal networks, like those related to ivory trafficking in recent years, could have a significant impact on perceptions of risk. For legislative design, there is guidance available on penalty and sentencing approaches to dissuade wildlife crime.\(^3^5\)

**Restorative justice**

An alternative approach that shows promise for crime prevention, specifically recidivism (re-offending), is restorative justice. Restorative justice is an approach that focuses on the rehabilitation of offenders by encouraging them to “accept responsibility for the harm caused by their actions to make themselves accountable to those they have harmed,” promoting reconciliation with the victim and the community at large who take part in resolving the situation.\(^3^6\) It has shown evidence of some effectiveness in decreasing repeat offending when carried out within a range of specified parameters. Careful attention is needed to manage any offender-victim meetings and the type of reparation requested. One study focused on recidivism behaviour for various groups of offenders in Australia. Offending by violent youths who participated in a restorative justice conference fell by 49 per cent, while offending for those assigned to traditional court processes only fell by 11 per cent. Offenders and victims reported the conferences to be procedurally fairer than court.\(^3^7\)

As documented in Chapter 3 of the current report, wildlife trafficking is not a victimless crime as people affected, including environmental defenders, can suffer loss of livelihoods, persecution, injury and loss of life as a result of wildlife offences. Examples in the current report indicate that innovation in criminal justice responses to wildlife crime is particularly worthy of consideration in deterring low-level participants in source countries. Illegal harvesting and trade in many wildlife goods often depends on occasional and sometimes opportunist participants in the wildlife trafficking chain. A pilot application under way in South Africa aims to trial restorative justice within communities where wildlife crime has impacted people and their natural heritage.\(^3^8\)

**Liability for remedying harm**

Complementary to criminal justice interventions, many countries also have existing legal provisions (within administrative, criminal and civil law) that can hold offenders legally responsible for remedying the harm
A growing number of cases around the world have operationalized these types of liability provisions for illegal wildlife trade cases in recent years, including against pangolin traders in Cameroon, illegal zoo owners in Indonesia, illegal fishers in France, and illegal recreational hunters in Thailand. Several additional cases are currently under way in five other countries.

Caused, including for the harm caused through wildlife crimes documented in chapter 3. Liability cases seeking remedies for harm have demonstrated success in changing the behaviours of environmental offenders in other contexts, notably pollution, where the increased costs and public visibility of court cases and providing remedies have had deterrent effects.

What is clear from an initial sample of 45 interviews is that while Indonesia has ramped up enforcement successfully, those incarcerated may not be the most prolific or high-ranking offenders (Figure 5.3). Two thirds of those interviewed claimed that the action leading to their arrest was their first involvement in illegal wildlife trade and only two were convicted reoffenders. The majority explained that they had been motivated by opportunity for supplementary income rather than livelihood necessity and that they had been aware that the activity they were involved in was illegal. In terms of deterrence, it is noteworthy that 21 of the offenders interviewed indicated that they did not worry about the effects of conviction on their social standing.

**BOX 5.3** Insights from wildlife crime offender interviews in Indonesia

In recent years, Indonesia has made great strides in improving its enforcement of wildlife crime laws, leading to numerous prosecutions and prison sentences for wildlife crime offenders. UNODC collaborated with the Indonesian prison service to interview offenders as part of a broader initiative for criminal justice reform to reduce prison overcrowding. The interviews focused on understanding how offenders got into wildlife poaching and trafficking, their modus operandi, and what would deter them from future criminal acts.

Two thirds of those interviewed claimed that the action leading to their arrest was their first involvement in illegal wildlife trade and only two were convicted reoffenders. The majority explained that they had been motivated by opportunity for supplementary income rather than livelihood necessity and that they had been aware that the activity they were involved in was illegal. In terms of deterrence, it is noteworthy that 21 of the offenders interviewed indicated that they did not worry about the effects of conviction on their social standing.

Understanding crime displacement

Crime displacement has been characterized as the relocation of crime from one place, time, target, offence, or tactic to another as a result of some crime prevention initiative. A systematic review of over a hundred situational crime prevention evaluations where spatial displacement was measured found that it only occurred in around a quarter. When spatial displacement did occur, on average, its impact tended to be less than the gains achieved by the intervention. Furthermore, in another quarter of the examples reviewed there was evidence of what criminologists refer to as a “diffusion of benefits.” This occurs when reductions of crime (or other improvements) are achieved in areas that are close to crime-prevention interventions, even though those areas were not actually targeted by the intervention itself. Further research on this topic concluded that it is more helpful to think about crime deflection, rather than displacement, with possible malign and benign outcomes that can be predicted in the design of prevention interventions. The scarcity of displacement is likely because it requires extra time, effort and risk, reduces rewards, and increases uncertainty on the part of offenders. Some offenders are unable, and others unwilling, to shift their activities. Insights into likely displacement effects can therefore be used strategically to deflect offenders to less harmful crime forms, and to delay crime, sometimes indefinitely.

Displacement of wildlife crime geographically and in terms of target species and smuggling methods was raised as a concern in the World Wildlife Crime Report 2020. These are certainly important trends to track, but learning from other crime types makes it clear that displacement is not necessarily a sign of failed intervention and that there is a lot to gain from detailed analysis of displacement outcomes. Wildlife populations have defined areas of distribution and availability, and some types of harvest opportunity may be seasonal. As is clear from the analysis of trafficking drivers in chapter 4, different wildlife market sectors have specific preferences. Shifting wildlife sourcing to a new location likely attracts increased costs leading to reduced criminal profits. Shifting to a new species may be a compromise in terms of market value. Evidence on displacement has strong potential to inform design of strategies to address different wildlife trafficking sectors.

Avoiding unintended consequences

Increasing the number of enforcers is not necessarily proven to reduce crime. Overall, there is some evidence of higher police numbers decreasing crime in the short-term but only if large-scale increases in policing numbers are seen—marginal changes in police numbers are seen—marginal changes in policing numbers most likely do not greatly alter crime levels. Increased enforcement can also have the negative consequence of inciting backlash from communities if the legitimacy of the increased enforcement and force used is not established. A review of learning from “tough-on-crime” sentencing policies concluded that such approaches may prove ineffective at reducing crime rates and recidivism, and that they can be harmful to individuals, communities, and state economies. There is also evidence, that law enforcement resulting in large numbers of arrests of low-level offenders may not necessarily have the hoped for impact of crime reduction and can incur high unintended economic and social costs.

These are particularly important lessons for wildlife crime given evidence that low-level offenders are incarcerated for offences in this sector, as discussed in chapter 3. Recent research carried out by UNODC probed this issue through interviews of offenders convicted of wildlife crimes in Indonesia (Box 5.3).

Sources of guidance

Several guides that outline step-by-step processes and factors to consider when designing interventions to counter wildlife crime are found on a website hosted by Arizona State University dedicated to the problem-solving approach to “wilderness problems” (which includes illegal wildlife trade and broader wildlife crimes). Content is peer-reviewed to the extent that the website is led by an editorial board of crime reduction specialists from both urban and wildlife crime backgrounds. Guidance is rooted in the evidence-based practice of problem-solving. Content includes: an overview guide on how to conduct problem-oriented wildlife protection; a problem analysis manual; guides for specific types of wildlife crime problems including wildlife poaching on US Federal Lands, illegal commercial fishing, methods
Crime script analysis is another tool increasingly used to help design illegal wildlife trade interventions. It employs a step-by-step review of how a specific crime is committed, identifying the complete sequence of choices and actions prior to, during, and after the crime and the links between them. Any specific crime, in terms of type and location, can be represented in a crime script as following a decision sequence with several broad stages from preparation through commission and aftermath. From a crime script, it is possible to determine which actors to target with interventions and where and when those interventions might be best implemented. Over a hundred published crime script studies include a range of wildlife crime examples, including some involving organized and financial crime. Further specific wildlife crime examples and guidance on use of crime scripts to address illegal wildlife trade are included in some of the aforementioned guidance sources.

The second edition of the International Consortium on Combating Wildlife Crime (ICCWC) Wildlife and Forest Crime Analytic Toolkit provides national and local government officials with guidance in five key areas: legal frameworks; law enforcement; criminal procedures and the court; international cooperation; and drivers and prevention. It allows government officials to assess national and local structures and procedures in comparison to international best practice and provides practical guidance for design and implementation of different interventions. Guidance is also available on design and implementation of interventions to address drivers of wildlife trafficking at source and in end markets. For example, the People Not Poaching online platform fosters learning and experience-sharing on supporting and engaging communities in initiatives to reduce poaching and illegal trade. On the demand side, a social and behavioural change community of practice operates an online platform to share knowledge on application of behavioural science approaches to reduce demand for illegally traded wildlife products.

Towards better insights into what works to address wildlife crime

There are clear advantages to be gained from enhancement of evidence about what works to address wildlife crime. Such knowledge can be used to prioritize, target, evaluate and refine wildlife crime interventions, employing the wide range of analytical and planning tools already in use in the wider crime prevention community. The evidence can be used to inform policy and other reforms to the enabling environment within which wildlife crime takes place. Every intervention then becomes an opportunity to understand “what works” and improve.

Among current obstacles to accumulation and use of such evidence, the most significant challenge is a lack of investment in monitoring and evaluation processes, including indicator development, data collection and structured assessment. Within relevant government systems, priority is usually given to direct operational intervention, with limited attention to collection and evaluation of associated crime data. Success is typically judged based on outcomes such as contraband seizures, and arrests and prosecutions, rather than through assessment of changes in crime levels, illegal trade volumes or reduction in associated harms like the recovery of threatened species populations.

Project-level interventions do usually require more rigorous monitoring and evaluation elements. However, they typically rely on limited baseline reference points and post-intervention data gathering. Even in cases where data are available, weaknesses in associated decision-making processes may lead to ineffective use of evidence, faulty decisions, wasting of resources, and the erosion of public and political support. This challenge is compounded by the fact that project funding cycles are typically too short to incorporate evidence-driven adaptive management cycles or rigorous assessment of harm reduction. Furthermore, monitoring and evaluation costs are often capped at relatively low levels in budgets.
Improved approaches to assessment of what works need to focus on two levels of evidence and evaluation, the direct process-related results of interventions made, and the consequent impact on crime levels and associated harms. Experience from other crime research indicates that spending adequate funds for strong evaluations in a few sites is far more cost-effective than spending little amounts of money for weak evaluations in thousands of sites, although caution is necessary in generalizing results on a wider scale.

Tools for tracking process-related results include the ICCWC Wildlife and Forest Crime Indicator Framework, which is structured under eight enforcement outcome measures and 50 individual indicators. It can be used to guide development of baseline measures, monitoring of progress, and evaluation of effectiveness over time. Similarly useful at this level are the ICCWC Guidelines for Wildlife Enforcement Networks, which include a comprehensive evaluation matrix.

At an impact assessment level, many wildlife crime studies report something about observed changes without establishing that the intervention caused that change. An example would be the observation that the number of arrests in a protected area increased and the number of wildlife carcasses detected decreased in a six-month period. While it is possible that the two are related, the causal link has not been established. Establishing that causal link would be best done through experimental or quasi-experimental evaluation designs that ask what would happen if there had been no intervention? Often, these designs require a control group or location where the intervention is not implemented to use for comparison with where it was. This could create ethical problems if a choice is made purposely not to help a location or group, although in reality, with limited resources for intervention, a non-intervention comparator will likely be available. However, if such experimental approaches are not feasible, the best solution may be to collect baseline data before an intervention and compare this to the same indicators post intervention. Nevertheless, a mix of indicators is needed to establish impact through triangulation (Box 5.4).

Evidence reviews indicate that data sources on wildlife crime are currently rather limited in terms of scope and accessibility compared to those available for other crime sectors for which policing results and crime

---

**BOX 5.4 Experimental learning**

A study in Kui Buri National Park, Thailand, covering the period 2008–2011 provides a good example of quasi-experimental methods being used where data are triangulated. Some 116 outreach events were held with the aim of decreasing local poaching. The interventions aimed to: build trust and raise awareness; offer opportunities for action; promote benefits and confidence that positive results were achievable; generate social pressure against poaching. Wildlife abundance was assessed for four species at three sites using both observational studies and camera trapping. Poaching pressure was recorded as the encounter rate of poaching signs per kilometre patrolled. The deterrent effect of the outreach was assessed by triangulating measures of patrol effort (mean number of days per month) and poaching for the months before and after outreach, along with an attitudinal survey of people in the area to learn about poaching involvement, motivations and perceptions of changing intensity. Two thirds (67 per cent) of respondents believed that community outreach had caused a decline in poaching.

While neither the simple before and after comparison of poaching levels, in the absence of a control site, nor the perceptions survey is perfect, they both point to similar results (a decrease in poaching, not due to an actual patrol increase). The limitations of such a design are that the results cannot be reliably assumed to be replicable in other contexts and ideally a control area is needed, but the study does provide an example of promising evidence being generated from a relatively simple design because it is strengthened by some element of triangulation and examination of evidence for the assumed mechanisms being activated.

---

perception and other surveys are available to researchers and the public in many jurisdictions. This is partly attributed to what has been termed the “silent victim syndrome”, whereby wildlife troubled by crime cannot “call the police” as other victims might do.78 As a result, evidence of wildlife crime is usually a product of enforcement effort. National datasets on wildlife crime are typically fragmented, short-term and difficult to access, with a bias towards information on seizures, particularly of CITES-listed species.79,80

Like arrest and conviction statistics that are sometimes available for wildlife crime offences and used as indicators of success, seizure data are a mixed indicator in that they illustrate the level of enforcement effort made as much as they indicate the extent of crime and illegal trade. They may also reflect embedded biases of enforcement efforts, including racialized and gendered presumptions. Furthermore, as noted earlier in this chapter, research from other crime fields indicates that seizure and arrest do not necessarily deter further criminal behaviour. Complementary measures of market data, such as price changes, retail availability and turnover, and changes in harm, such as poaching levels and wildlife population impacts, are necessary to extend the utility of such data.82 Triangulation with less direct measures can help to check logically whether mechanisms have been activated, and whether those mechanisms are therefore likely to be achieving some impact.82

The absence of accessible baseline data on a range of metrics along the illegal wildlife trade chain is a persistent concern.83,84 It is generally not practical for the costs of pre-intervention monitoring and data compilation to be absorbed into budgets for discrete enforcement actions and support projects. A community of practice approach for collation and sharing of data for key variables, such as wildlife population trends, market indicators and criminal justice results could greatly boost evaluation of wildlife crime interventions overall.

Another topic worthy of greater investment in evidence gathering and analysis is the performance of law enforcement, prosecution and sentencing processes related to wildlife crime within criminal justice systems. Factors of interest include the impact of corruption, identification of process obstacles and gaps, and ultimately the evidence for impact on criminal behaviour.85

Overall, there is a clear case that priority-setting and tactics would benefit from stronger evidence. Climate science provides an informative example of how progress in the accumulation, collaborative analysis and policy use of evidence for problem-solving can be achieved.86 For wildlife crime this will require investment in data gathering and analysis and stronger cooperation between relevant agencies, including multilateral, government, civil society and academic institutions. It will also require prioritization by funding agencies.

Putting current learning into action

Despite evidence gaps, wildlife crime reduction policies are being implemented by regulatory and enforcement agencies and funding institutions are making decisions about investments in related interventions. Since multi-faceted approaches appear to be effective in reducing other types of crime, these efforts are unlikely to be in vain. Furthermore, this chapter demonstrates that there is a growing body of research on the effectiveness of different wildlife crime responses and that useful insights are emerging. The lessons from such work should be put to use.

For example, evidence-based analysis illustrates how different factors influence the impact of anti-poaching patrolling in certain locations and how multifaceted enforcement and market interventions are contributing to reductions in ivory trafficking and elephant poaching. Such findings can already be used to help inform intervention design in other places and for other trafficked commodities. There is also a wide range of useful knowledge to draw from insights already developed for other crime sectors. For example, displacement of wildlife crime between places and species may not simply be a sign of failure, systematic situational analysis can guide effective intervention design and effective deterrence requires action beyond seizures and arrests. Again, such learning can be applied now. A call for better evidence is not a case for inaction due to uncertainty.
Endnotes

A systematic mapping study is a process of identifying, categorizing, and analyzing existing literature relevant to a particular research topic to gain insights to existing evidence and guide future research.

4 Staff from the United States Fish and Wildlife Service (USFWS) and the Canadian Centre for Evidence-Based Conservation collaborated with a diverse team of expert advisors to screen and analyse published evidence.

</table>
This third edition of the *World Wildlife Crime Report* probes recent trends in the illicit trafficking of protected species of wild fauna and flora and provides a broad assessment of current knowledge about the causes and implications of associated crime at a global level.

As with the first two editions, published in 2016 and 2020 respectively, research carried out for this report included quantitative market assessment and a series of in-depth case studies. The findings inform an overview of recent characteristics and trends in global wildlife crime and provide insights into the dynamics of how it is affecting selected wildlife species. Additional emphasis for this edition is on systematic analysis of wildlife crime harms and impacts, factors driving crime trends, and the evidence for what remedial interventions work best.

The report was prepared in response to the United Nations General Assembly Resolution on Tackling Illegal Trafficking in Wildlife adopted in 2021. This resolution requested the United Nations Office on Drugs and Crime (UNODC), in close cooperation and in collaboration with Member States, to continue and strengthen the collection of information on patterns and flows of illicit trafficking in wildlife.

*With the support of*

*The International Consortium on Combating Wildlife Crime (ICCWC)*
